Journal of the Society of Chemical Industry.

INDEX OF VOL. XI.—1892.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a Patent.

A		PAGE	André, G. G. See Curtis.....		PAGE
			André, G. G., and Curtis, C. H. Manufacture of Gunpowder (P).....		180
			Andreef, A. See Andres.....		705
			Andres, G., and Andreef, A. Russian Peppermint Oil and Methylamine.....		705
			Andrew, R. Aerators for Treating Liquids (P).....		896
			Andrews, T. The Passive State of Iron and Steel. Part II. (illus.).....		527
			Part III.....		609
			Amnison, F. G. Treatment of Paper, Linen, and other Textiles (P).....		904
			Appenzeller, E., and Fillenl, E. Apparatus for Testing the Strength of Fibres (P).....		680
			Appert, L. Manufacture of Glass Pipes of large Diameter.....		38
			Applegarth, E. See Atkins.....		43
			Archbutt, L. Discussion on Impurities in Coal-Gas.....		420
			Discussion on Pipe-clay Triangle.....		326
			Discussion on the Estimation of Silica in Clay.....		217
			Proceedings of the Annual General Meeting.....		577
			See Deeley.....		595
			The Estimation of Silica in Clay.....		215
			Archbutt, L., and Deeley, R. M. Treating Chemically Softened Water (P).....		421
			Armand, A. See Grimaux.....		631
			Armitage, Sir E., and Sons, (Linn.), and Dunkerley, P. Manufacture of Cloth for Press and Filtering Sheets (P)...		908
			Armour, L. H. Ovens or Retorts for Making Coke or Charcoal or Distilling Carbonaceous Matter (P).....		152
			Ovens, Retorts, Furnaces, &c. (P).....		806
			Armstrong, C. Kilns for Burning and Glazing Sanitary Ware (P).....		524
			Armstrong, G. E. Composition for Treating Fibrous Material (P).....		928
			Armstrong, H. E. See Robertson.....		695
			The Chemical Changes attending Photographic Operations.....		455
			The Origin of Colour.....		512
			Armstrong, H. E., and Kipping, F. S. Camphrene: a Product of the Action of Dehydrating Agents on Camphor.....		57
			Armstrong, J. Manufacture of Tanks, &c., of Glass (P).....		695
			Armstrong, R. Manufacture of Detergent Powder (P).....		536
			Arnaud, A. A New Unsaturated Fatty Acid.....		619
			See Grimaux.....		631
			Armstrong, J. J. Note on Scouring Wool.....		29
			Arnold, J. Discussion on the Acid Action of Drawing Papers.....		214
			Arnold, T. Utilisation of Slag (P).....		819
			Asboth, A. von. Estimation of Sulphure Acid in Sulphates ..		714
			Archarow, J. Estimation of the Organic Substances in the Air.....		464
			Aschoff, K. See Jaamasch.....		458, 458, 845, 845
			Askham, J. U. Grinding and Crushing Apparatus (P).....		994
			Askenasy, P., and Meyer, V. Photo-Chemical Notes.....		1039
			Slow Combustion of Gaseous Mixtures.....		1039
			Astrop, W., and Parker, F. H. Manufacture of Carbonate of Lead or White Lead (P).....		45
			Atkins, G. A. Separating Gold, Silver, and other Metals from Ores (P).....		618
			Atkins, G. J., and Applegarth, E. Separating Alkaline and Earthy Metals from their Salts, &c. (P).....		43
			Attout, P. A. Distilling and Apparatus therefor (P).....		508

	PAGE		PAGE
Aubin, E. Separation and Estimation of Lead, Silver, and Zinc in Minerals composed of Galena and Blende	775	Bayard, G. D. See Harvey	966
Augustenborg, J. J., and Hansen, R. Apparatus for Testing Milk (P)	52	Bayrac, P. H. Indothymol: Preparation of Thymoquinone	996
B			
Bachem, A., and others. Apparatus for Glazing Paper (P)	935	Beadle, C. Discussion on Fluid Specific Gravity Determination	304
Bader, K. Method for Alkalimetric Estimation of Phenol	273	Speech at Annual Dinner	583
Badische Anilin und Soda Fab. Basic Dyestuffs from Alphanaphthoquinone-dichlorimide	309	The Acid Action of Drawing Papers	261
Manufacture of Basic Naphthalene Colouring Matters, and Sulpho-Acids thereof (P)	516	Beadle, E. See Ruston	267
Manufacture of Hydrazine or Diamidogen and its Salts (P) ..	370	Beales, H. Copying Inks, Copying Books and Appliances (P) ..	45
New Dyes of the Rosaniline Series and New Materials thereof (P)	515	Beard, W. J. See Scott	903
Production of Azo-Dyes and Materials thereof (P)	1000	Beare, T. H. The Building Stones of Great Britain	1011
Production of Dyes belonging to the Rhodamine Series, and Materials thereof (P)	315	Beauharnais, E. de. Manufacturing Illuminating Gas (P)	234
Production of Dyestuffs (P)	236	Beaumann, A. Application of Coal-Tar Colours in Paper Dyeing	159
Production of Morant-dyeing Colouring Matters related to the Rosaniline Series (P)	236	Bechamp, A. Action of Light on Silver Chloride	266
Production of New Basic Dyestuffs (P)	514	Becker, H. See Quertain	449
Production of New Diazo-Dyes, &c. (P)	514	Bequerel, H. On the Measurement of High Temperatures ..	709
Production of New Dyes related to the Rhodamine Series (P) ..	740	Bedson, P. P., and McConnell, W. On the Gases Enclosed in Coal	882
Production of New Sulpho-Acids and Colouring Matters therefrom (P)	679	Beilby, G. T. Manufacture of Cyanides (P)	747, 1004
Badt, F. B. Practical Notes on the Electrolytic Refining of Copper	926	Bell, C. E. Coke Ovens (P)	906
Baeyer, A. von. Quinitol, the Simplest Sugar of the Inositol Group	700	Bell, J. Carter. Analysis of Snow from Neighbourhood of Chemical Works	320
Bailey, G. H. Discussion on Testing Coal-Gas	414	Discussion on Action of Chlorine on Wool	131
The Impurities of Town Air	789	Discussion on Estimation of Zinc	133
Bailey, J. M. Apparatus for Production of Fuel Gas	800	Discussion on Testing Coal-Gas	414
Baker, H. B. Action of Light on Silver Chloride	634	Bell, Sir Lowthian. The Manufacture of Iron in its Relations to Agriculture	819
Baldensperger, T. Turkey-Red Dyeing	237	Belleruche, E. Durability of India-rubber Hot-water Pipes ..	929
Ball, E. J., and Wingham, A. Elimination of Sulphur from Iron	751	Benedikt, R. Analyse der Fette und Wacharten	65
Ball, J. B. The Manufacture of Oil-Gas	896	Analysis of Galena and Lead Sulphate	181
Ballantyne, H. See Thomson	506	Benoit, E. J. B., and Salery Vela, J. Extracting Stearine and Oleine from Tallow (P)	620
Ballinghall, D. See Mirreles	885	Bentz, E. See Watson	450
Bamher, H. K., and others. Portland Cement and Portland Cement Concrete	1007	Berg, C. Manufacture of Bronze Ingots, &c. (P)	1013
Bamberger, E. Addition of Hydrogen to Tricyclic Systems	23	Berge, A. H. J. Apparatus for Converting Amylaceous Substances into Soluble Products (P)	448
Bamberger, E., and Goldschmidt, C. Ethyl- α -Naphthylamine ..	23	Bergh, A. Subjecting Liquids having Substances suspended in them to Centrifugal Action (P)	337
Bamberger, E., and Kitchelt, M. Action of Hypochlorous Acid on β -Naphthoquinone	997	Berkenheim, A. Menthol	632
Bamberger, E., and Stettenheimer, L. "Aromatic" Octahydro- α -Naphthoquinoline	24	Berlioz. See Yven	264
Tetrahydro- α -Naphthoquinoline	23	Berly, A. Improvements in Analysing Columns (P)	803
Bamberger, M. Exorescent Resins	365	Berk, H. Filtering Apparatus for Oil, &c. (P)	536
Bancroft, A. Manufacture of Textile Articles with Fringed Edges (P)	518	Berthelot. Iron Carbonyl	909
Bang, Asaprol	837	Nickel Carbonyl	909
Banks, W. J. B. Compound for Insulating, &c. (P)	927	On the Oxidation of Nickel Carbonyl	438, 946
Barber, F. M. High Explosives in Warfare	59	Persulphuric Acid and its Salts	946
Barclay, H. Determination of Loss of Coal in Washing Operations	325	On the Existence of Acid and Basic Salts in very Dilute Solutions	465
Barkley, R. See Stones	1006	Berthelot, Gantier, and Duclaux. Report on the Dephastering of Wine	543
Barlow, B. Drying Brewers' Refuse (P)	932	Bertram, J. Obtaining the two Isomeric Monomethylethers of Protocatechuic Aldehyde (P)	58
See Cunnille	450	Bertram, J., and Walbaum, H. The Oils of Lavender and Bergamot	838
Barnett, D. Apparatus for Treating Textile Vegetable Substances (P)	810	Bertram, L. Extracting Glue and Grease from Hide and Skin Waste and Bones at Low Temperature (P)	447
Barringer, H. See Redwood	599	Bertrand, G. Identification of Xylose and Distinction from Arabinose	1035
Barrow, J. Discussion on Cost of Sewage Treatment	10	On some Colour Reactions of the Carbohydrates	272
Purification of Sewage by Precipitation	1	Bertrand-Leplat, J. Apparatus for Dyeing or Bleaching (P) ..	161
Barrows, A. E., and Turner, T. Estimation of Slag in Wrought Iron	636	Bertrand, P. H. Forming Magnetic Oxide on the Surface of Iron (P)	634
Barth, Dr. Report on the General Character of German Wines ..	763	Beste, E. Magnesium Flash-Light Apparatus (P)	899
Barton, J. Mashing and Brewing Fermented Liquors (P)	838	Betting, C. F. Assay or Chemical Balances (P)	635
Basanta, H. Coil for Feeding Syrup or Molasses into Vacuum Pans (P)	512	Bevan, E. J. Discussion on Electrolytic Chlorine and Soda ..	965, 966
Eastin, M. C. Estimation of Manganese in Spiegel Iron and Ferro-Manganese	1037	Discussion on the Acid Action of Drawing Papers	214
Bates, F. G. Metallurgical Furnaces and Ovens (P)	615	See Cross	213, 214, 963, 966
Bates, H. Production of an Alimentary Product from Maize (P) ..	769	See Menzies	175
Bathgate, G. Closing Vessels for Preservation of Foods (P) ..	629	Beveridge, J. Treating Fibrous Plants for Manufacture of Paper Pulp (P)	176
Baudisch, J. Quantitative Determination of Mechanical Wood Pulp in Paper	464	Beyer, B. Manufacturing Yarns, &c. from Waste Silk (P)	168
Bauer, H., and Gyiketta, J. Production and Application of Boron Sulphate Compounds (P)	930	Bibby, J. Manufacture of Compound Cakes for Cattle (P) ...	768
Bauer, T., and Mendheim, G. Coke Ovens (P)	737	Bibby, J. H. Smelting Copper or Copper Ores, and Furnaces thereof (P)	922
Baur, A. Discussion on Artificial Musk	308	Biekes, T. See Jannasch	547
Manufacture of Artificial Musk (P)	773	Bidder, G. P. Analytical and other Delicate Balances (P)	1035
Studies on Artificial Musk	306	Bidelman, R. M. Manufacture of Gas (P)	996
Bantmy, B. See Neucks	837	Biedermann, Rudolf. Technisch-Chemisches Jahrbuch	185
Baxter, J., and W. Means and Apparatus for Refining Paraffin (P) (illus.)	424	Biernath, E. Heat Insulating and Waterproof Material (P) ..	908
		Biggart, J. W. Composition of "Hunyadi Janos" Mineral Waters	336
		Discussion on Composition of Mineral Waters	336
		Discussion on Vulcanisation of Rubber	335
		Biggs, B. Discussion on Destructive Distillation of Wool	403
		Bigland, C. H. Paints for Ships' Bottoms, &c. (P)	538
		Bigot, C., and Schreiner, J. Manufacture of Sodium Borates (P) ..	434
		Billings, A. W. Apparatus for Manufacture of Malt Liquors (P) ..	833
		Manufacturing Beer and Ale (P)	628

	PAGE		PAGE
Binder, F. Production of a Discharge on Dyed Indigo.....	813	Briggs, E. Shower-Proof Fabric (P).....	904
Binney, E. Manufacture of Lamp-black Carbon-black (P)...	171	Briggs, J. Kilns for Burning Limestone, Cement, &c. (P)....	606
Biolytic Gypse, Co., The. Insecticide and Fertiliser (P).....	541	Briggs, W. A. Cement Composition for Interiors of Ships (P).....	749
Birch, W. Apparatus for Cleansing Sewage and other Liquids (P).....	364	Brindley, G. F. Solid Compounds of Sulphur Trioxide, Water, and the Bisulphates or Acid Sulphates of Sodium or Potassium (P).....	1004
Bird, F. Apparatus for Drawing off Liquid from Sewage-Tanks (P).....	630	Briu's Oxygen Company, Limited, and Murray, K. S. Preparation of Materials for Separation of Oxygen and Nitrogen from Atmospheric Air (P).....	936
Bird, H. Manufacturing Blocks or Bricks from Purple Ore (P).....	694	Brisson, G. Progress of Steel-making in Austria-Hungary....	609
Bischoff, C. A., and Hausdörfer, A. <i>p</i> -Tolylglycine.....	808	Brittingham, W. B. Bleaching Compound (P).....	716
Bittó, B. von. Reaction of Sodium Nitroprusside with Aldehydes and Ketones.....	846	Detergent Compounds (P).....	758
Black, A. F. Apparatus for Treating Sewage (P).....	630	Broadbent, J. K. Apparatus for Regulating Admission of Air and Steam to Furnaces (P).....	836
Blackall, W. See Alsop.....	895	Brochet, A. Pyrogenic Hydrocarbons formed in the Manufacture of Compressed Gas.....	596
Blackham, W. P. See Rees.....	704	Brochocki, T. Manufacture of the Peroxides of Barium and Hydrogen (P).....	707
Blair, G. Y. Evaporating Apparatus (P).....	992	Brock, J., and Marsh, J. T. Manufacture of Carbonates of Strontium and Barium (P).....	1005
Blair, T. S., jun. Reduction of Ores (P).....	614	Brokhoff, R. Manufacturing Sugar (P).....	626
Blakey, T. W. See Mason.....	436	Bromilow, J. Gas Producers (P).....	806
Blaye, J. P. A. Treatment of Ramie Fibre, &c. (P).....	903	Brook, E. Machine for Dyeing One or More Warps (P).....	1004
Blenkinsop, W. E. B. See Hartley.....	170, 445	Brook, Simpson, and Spiller, Limited, and Green, A. G. Production of New Bases and of Azo-Colouring Matters therefrom (P).....	513
Bloemendaal, C. Producing Hydraulic Mortar (P).....	688	Brookes, A. G. See Read, Holliday, and Son.....	679
Blount, Bertram. Discussion on Destructive Distillation of Wood.....	401	Brookman, Geological and Economical Conditions of the Westphalian Coal-Beds.....	338
Discussion on Electrolytic Chlorine and Soda.....	965	Brooks, B. Machine for Preparation of Brewers' Finings (P).....	700
Bloxham, A. G. Proceedings of the Annual General Meeting.....	577	Brotherton, J., and Griffith, W. Holders for Quicksilver, Gas, and Fluids under High Pressure (P).....	993
Blumer, J. See Schlagenhauer.....	699	Brougier, A. See Wilhelm.....	768
Boake, A., and Roberts, F. G. A. Manufacture of Acid Sulphites (P).....	907	Brown, A. Crum. Discussion on Cellulose.....	223
Bohn, W. D. Apparatus for Leaching Ores (P).....	352	Brown, A. J. Influence of Oxygen and Concentration on Fermentation.....	257
Bolt, W. Tanning Hides or Skins (P).....	171	Brown, J. See Reynolds.....	105
Bone, W. A. See Lean.....	995	Brown, J. Campbell. Discussion on Legislation on Noxious Gases.....	123, 312
Bongartz, J. Percentage of Guaiacol in Wood Creosote, &c.....	511	Discussion on Technology of India-Rubber.....	974
Bouta, J. W. Lenses or Annealing Furnaces for Glass (P).....	818	Models of Metallurgical Furnaces.....	312
Borgarelli, G. Apparatus for Drying and Disinfecting Grain (P).....	230	Proceedings of the Annual General Meeting.....	571
Bornträger, A. Apparent Proportion between Dextrose and Levulose in certain Wines.....	766	Brown, S. H. Compound for Carbonising Metals (P).....	616
Effect of Presence of Lead Acetate on the Titration of Lactose.....	778	Browning, P. E. Quantitative Separation of Barium from Calcium.....	777
Influence of Acetates of Lead on the Estimation of Invert Sugar.....	778	Brownlow, R. S. Apparatus for Purifying Water and other Liquids (P).....	769
Potassium Hydrogen-tartrate as a Starting Point for Acidimetry and Alkalimetry.....	776	Bruck, E. Detection and Removal of Protein Substances in Beet Juice by Means of Tannin.....	830
Borrger, C. Construction of Bricks (P).....	689	Bühli, J. W. An Alcohol of Antipyrine.....	632
Bott, J. E. Manufacture of Ferro-Bronze and other Alloys (P).....	693	Determination of Specific Gravity of Viscid Substances... ..	60
Manufacture of Salt (P).....	1005	Investigations of Terpenes and their Derivatives.....	638
Bottone, T. D. Casting and Tempering Pure Copper (P).....	615	Terpenes and their Derivatives.....	705
Bouchardat, G., and Lafont, J. Action of Benzoic Acid on Turpentine.....	262	Vacuum Desiccator with Heating Arrangements.....	60
Boulet, G. See Donard.....	804	Brunner, H. Address to Liverpool Section.....	874
Boult, A. J. Manufacture of Size Paint (P).....	361	Discussion on Technology of India-Rubber.....	974
Bourne, T. F. See Moss.....	174	Speech at Annual General Meeting.....	577
Bowers, W. H. Retorts for Carbonisation of Wood, &c. (P) ..	152	Brunner, L., and Zanner, A. Manufacturing Nitrate of Ammonia or Chloride of Ammonia and By-Products (P).....	37
Bowes, A. Discussion on Cost of Sewage Treatment.....	9	Simultaneous Production of Neutral Sulphate of Soda and Precipitated Phosphate of Lime (P).....	816
Bowley, J. W. Apparatus for Producing Cold (P).....	992	Brunner, O. Waterproofing Leather (P).....	233
Bowman, Dr. Discussion on Manufacture of Oxygen Gas.....	319	Bruns, C. H. W. Manufacture of Colours, specially applicable for Photographs (P).....	679
Bowman, F. H. Discussion on Testing Coal-gas.....	414	Buchanan, J., jun. Discussion on Noxious Gases Legislation ..	312
Bourgois, N., and Deceure, H. Apparatus for Making Gas (P).....	596	Bucher, E. See Schweich.....	515
Boyd, Nelson. Discussion on Galician Petroleum and Ozokerite.....	118	Buchet, C. Lead in Tartaric Acid.....	837
Boyer, C. S. Analysis of "Egizio".....	447	Buchner, E. The Chemistry of Fermentation.....	763
Boyer, E. Determining Nitric Nitrogen and Total Nitrogen..	182	Bucket, M. Detection and Estimation of Lead in Commercial Tartaric and Citric Acids.....	818
Bradburn, J. A., and Pennock, J. D. Manufacture of Alumina (P).....	37	Buckley, W. Machines for Printing Calico, &c. (P).....	160
Brand, E. Manufacture of Animal Glue (P).....	930	Budenberg, C. F. On Risks attending Use of High-Pressure Gases.....	319
Brandt, Preventing Formation of Oxycellulose in Printing Discharges on Indigo Blue.....	33	Bugg, F. J. Improved Compound Fabric (P).....	518
Brandt, C. F. Process for Discharge of Dyed Indigo-Blue.....	812	Bull, H. C. Electric Batteries (P).....	826
Red and White Discharge Prints on Dyed Indigo-Blue.....	812	See Hossack.....	630
Brank, E. von. New Explosive Compositions (P).....	456	Burghardt, C. A. Pigments having a Lead Basis (P).....	361
Braun, O., and Liebreich, O. Manufacture of Fatty Matter from Wool Fat (P).....	445	Burkel, A., and Osterwald, C. Composition for Blotting or Absorbing Liquids (P).....	176
Bredel, F. See Klönne.....	597	Barnet, L. Evaporators and Feed-Water Heaters (P) (illus.).....	422
Bredig, G. See Wagner.....	1032	Burns, P. S., and Hull, C. S. Application of the α -Sulphonic Acid of Naphthalene to Bating and Paring Skins (P) ..	48
Brestowski, A. Handwörterbuch der Pharmacie. 275, 374, 641.....	782	Buron, L., and Marchand, P. Composition for Fixing Ammoniacal Nitrogen (P).....	1018
Breuer, A. Diaphragms for Electrolytic Decomposing Apparatus (P).....	927	Busch, A. Hydraulic Cements.....	164
Breuer C. Manufacturing Artificial Stones with Glass Surfaces (P).....	241	Busch, M. See Fischer.....	24
Brewing Improvement Co., The. Treatment of Hops, and their Use in Brewing (P).....	932		
Briant, L. See Hatschek.....	258		
Briart, A., and Jacquemin, P. Enriching Calcareous Phosphates and Manufacturing Superphosphates (P).....	816		
Brice, R. J. Using Galvanisers' Wastes (P).....	413		
Bridgman, H. L. Mixer and Divider for Ore Samples (illus.).....	268		
Brier, H. Means for Obtaining Oxygen and Nitrogen from the Air (P).....	838

Anthraquinone—*cont.*

Manufacture of Colouring Matters Derived from. (P) Willcox. From the Farb. vorm. F. Bayer and Co.	513
Manufacture of Dyestuffs Derived from. (P) Willcox. From the Farb. vorm. F. Bayer and Co.	29
Antifebrin. (Trillat)	1029
Antimony and Copper, Simultaneous Electrolytic Deposition of. (Hampe)	695
Arsenic and Tin, the Separation of. (Clark)	461
Influence of, on Ductility, Strength, and Conductivity of Copper. (Hampe)	1014
Ores, Analysis of. (Carnot)	636
Ores, New Method for Assay of. (Carnot)	941
Pentaspilide of. (Willm)	758
Separation of, from its Ores. (P) Warwick	533
Smelting, The English Process of. (Rodger)	16
Solution of Chloride of, in Saturated Solutions of Sodium Chloride. (Casse)	600
Statistics Respecting. (T.R.)	81
Antipyrin. (Trillat)	1030
A Direct Method of Preparing. (Michael)	838
An Alcohol of. (Brühl)	632
A Nitro-Derivative of. (Jandrier)	706
Relation of β -methylamido-crotonanilide to. (Knorr and Taufkirch)	706
Sulphonic Acids. (Möllenhoff)	835
Antiseptic, A Soluble Naphthol. (Stackler)	772
Properties of Formic Aldehyde. (Trillat)	772
Antisepsis, Apparatus for Use of Liquid. (P) Herscher	631
Behaviour of, towards Salivary Digestion. (Weber)	834
Etc., from Coal Tar or Aromatic Oils. (Trillat)	1027
Soluble Quinoline. (P) Lembach and others.	452
Apatite. (Wills)	698
Apatites, Occurrence of Fluorine in. (Carnot)	759
Apparatus (Class I.) 20, 147, 230, 337, 421, 507, 595, 667, 733, 802, 894, 992 For Heating Liquids and Generating Vapour. (P) Watkinson	337
Apples, The Lixivation of, in Cider-making. (Jay)	1019
Appliances for Use with Incandescence Lamps. (P) Heald	735
Apricot a Yields of Tannin. (Mafat)	621
Arabinose, Distinction of, from Xylose. (Borland)	1035
The Fermentation of. (Frankland and MacGregor)	627
Arbousier a Yields of Tannin. (Mafat)	621
Are Light Carbons, Increasing the Life and Efficiency of. (P) Garland	43
Areca-nut, The Alkaloids of the. (Jahns)	57
Argentina, Drug Exports from. (T.R.)	167
New Customs Tariff of. (T.R.)	190
Argentine. (Harpf)	55
Republic, Drug Imports into the. (T.R.)	467
Aristol. (Trillat)	1028
Aristolochia a Yields of Tannin. (Mafat)	621
Armise a Yields of Tannin. (Mafat)	621
Arnica a Yields of Tannin. (Mafat)	621
Aromatic Octohydro-a-naphthoquinoline. (Bamberger and Stettenheimer)	24
Arsenic, Antimony, and Tin, Separation of. (Clark)	461
Influence of, on Ductility, Strength, and Conductivity of Copper. (Hampe)	1014
Quantitative Determination of. (Sauer)	370
The Role of, in Tanning. (Sadlon)	171
Artichoke a Yields of Tannin. (Mafat)	621
Articles of Interest to Technologists. (T.R.) 69, 190, 651, 729, 787, 951	
Asprol. (Bang)	837
Asbestos, Plates of, for Roofing Purposes. (P) Graf	212
Porcelain. (Garros)	162
Aseptol. (Trillat)	1028
Ash a Yields of Tannin. (Mafat)	622
Ashe Country, N.C., The Magnetic Ores of. (Nitze)	246
Asphalte, Artificial. (Valenta)	170
Mastic, Means of Securing as a Coating on Building Materials. (P) Haarmann	819
Assay, On the Preparation of Samples of Rich Argentiferous Lead for. (Pattinson)	321
Or Chemical Balances. (P) Betting	635
The Cornish. (T.R.)	470
Ton, Use of the. (Lowe)	133
Assays, Employment of Cadmium in Gold Bullion. (Whitehead)	458
Asphaltum, Manufacture of. (P) Dubbs	512
Atmosphere, Ammonia in the. (Muntz)	551
Gravimetric Method for Ascertaining the Composition of. (Leduc)	270
Atropine and Hyoscyamine. (Schütte)	453
Nitro-. (Einhorn and Fischer)	706
Australia, Natural Coke in	510
Austria-Hungary, Steel-making in. (Brisson)	609
Austria, Mineral and Metallurgical Output of, in 1891. (T.R.)	853
The Paper Industry of Lower	175
Aya-papa a Yields of Tannin. (Mafat)	621
Azine Green, Application of. (von Perger)	30
Azo-Colours and Azo-Dyes. See Colouring Matters.	
Azobitumin Paper. (Dietl)	635
Azonium-Bases. (Witt and Schmidt)	901

B

<i>Bacillus ethaeticus</i> , Fermentation of Arabinose by. (Frankland and MacGregor)	627
Bacteria and Fermentation—Yeasts—The "Ginger-Beer" Plant. (Marshall Ward)	255
Bahamas, Fertilisers in the. (T.R.)	1042
Baking Powders, Making up or Packing. (P) Clotworthy	259
Baku, The Petroleum Industry at. (T.R.)	1043
Balance, Betting's. (Groscurth and Luboldt)	215
Balance, Analytical and other Delicate. (P) Bidder	1035
Assay or Chemical. (P) Betting	635
Baltimore Meeting of American Institute of Mining Engineers	233, 246, 255
Bamboo a Yields of Tannin. (Mafat)	622
Bancoul a Yields of Tannin. (Mafat)	622
Bank Notes, Paper for. (P) Schlumberger	935
Barium chloride, Manufacture of. (P) D'Andria	36
Manufacture of Carbonate of. (P) Brock and Marsh	1005
Manufacture of Peroxide of. (P) Brochowski	707
Preparation of Anhydrous Oxide of. (P) Brin's Oxygen Co. and Murray	936
Quantitative Separation of, from Calcium. (Browning)	77
Barks, Analysis of New Cinchona. (Howard)	837
Baryta-Water, Explosive Compound formed by Action of, on Chromic Acid. (Pechard)	180
Barry Sewage Process. (Grimshaw)	6
Bars and Hoops, Galvanising Iron and Steel. (P) Jones	612
Bases, Action of Alkaline, on Solubility of Salts of the Alkalis (Engel)	237
Applicable for the Production of Substantive Cotton Dyes. (P) Abel. From Durand, Huguenin, & Co.	809
Determining Number of NH_2 Groups in Certain Organic. (Meldola and Hawkins)	640
Production of New, and of Azo-Colouring Matters therefrom. (P) Brooke, Simpson, and Spiller Lima, and A. G. Green	513
Production of Alkaline or Earthy Alkaline, by Electrolysis. (P) Hermite and Dubosecq	1015
Schiff's. (Miller and Plochl)	901
Basic Furnace Lining and Basic Material. (P) Alzugaray	922
Open Hearth Furnace, the "Ore Process" in the. (Leo)	243
Bath, A Porcelain Water. (Dittmar)	181
Batteries, Various:—	
Accumulators, Electric. (P) Lake. From La. Soc. d'ite Electriciteits-Maatschappij	755
Accumulators, Improvements in Electric. (P) Lamber	43
Accumulators, Purification of Sulphuric Acid for. (Kugel)	826
Accumulating or Storage. (P) Thompson. From Correns	535
Accumulators or Secondary. (P) Hauser	249
Accumulators or Storage. (P) Eliason	354
Accumulators or Storage. (P) Thompson. From Edgerton	249
Apparatus for Supplying Depolarising Liquids to a Series of. (P) Jeanty	617
Automatic Regulating Apparatus for. (P) Johnson. From Gendrou	354
Construction of Secondary. (P) Lee	827
Dry Galvanic. (P) Lesenberg and von der Poppenburg	927
Electric. (P) Harris and Power	354
Electric. (P) Scheithauer	249
Electric or Galvanic. (P) Lamb	249
Electric Primary. (P) Rawlins and Walker	43
Galvanic. (P) Cohen	755
Galvanic. (P) Hadden. From Cabanyes	354
Galvanic. (P) Manns and Smith	248
Galvanic. (P) Mureus, Patz, and Grebner	354
Galvanic. (P) Numan and Nelson	1016
Galvanic. (P) Poudroux	248
Galvanic, for Producing Constant Currents. (P) Wensky	248
Improved Galvanic. (P) Fischer. From Thompson	41
Improvements in Galvanic. (P) Engledue	617
Improvements in Electric. (P) Bull	826
Improvements in Galvanic. (P) De Meritens	43
Improvements in Galvanic. (P) Hardingham. From Hard and Connell	618
Improvements in Galvanic. (P) Souther	616
Improvements in Secondary. (P) Goward	43, 43
Improvements in Secondary. (P) Lake. From Schleicher and Mosher	618
Improvements in Voltaic. (P) Jablochkoff	617
Portable Galvanic. (P) Stiens	927
Primary. (P) Maquay	248
Primary Voltaic. (P) Weymersch	755
Secondary. (P) Colgate	927

Statistics Respecting. (T.R.)	80
Treating Composite Ores Containing. (P) Hart	352
Treating Ores and Residues Containing. (P) Clark. From Costs and others	352
Treating Waste Liquors to obtain. (P) Hall	613

INDEX OF NEW BOOKS.

	PAGE
Adressbuch und Warenverzeichnis der Chemischen Industrie des Deutschen Reichs. Wenzel	781
America, The Phosphates of. F. Wyatt. Second Edition	184
Ammoniak-Fabrikation, Taschenbuch für. G. Lunge	946
Analyse der Fette und Wacharten. Dr. R. Benedikt	65
Analysis, Commercial Organic. A. H. Allen. Vol. III., Part II. Second Edition	947
Manual of Qualitative Blow-Pipe. F. M. Endlich	1040
Analytischen Chemie, Kurzes Lehrbuch der. von Miller and von Kiliani	65
Anilinschwartz. E. Noeltzing and A. Lehne	276
Anleitung zur Chemischen Analyse Organischer Stoffe. Dr. G. Vortmann	373
Anorganische Chemie, Zeitschrift für. G. Kruss	374
Brewers, A Handy Book for. H. E. Wright	1040
Brewing, Text-Book on the Science of. E. R. Moritz and G. H. Morris	66
Blow-Pipe Analysis, Manual of Qualitative. F. M. Endlich	1040
Carbon Compounds, Chemistry of the. V. von Richter. Translated by Edgar F. Smith	185
Chemical Calculations, with Notes, Problems and Answers. R. Lloyd Whiteley	275
Lecture Experiments, Non-Metallic Elements. (G. S. Newth)	1040
Chemisch Technisches Repertorium, 1890. Dr. Emil Jacobsen	65
Chemistry, A Treatise on. Roscoe and Schorlemmer Vol. III., Part VI.	373
Lessons in Elementary. Sir Henry E. Roscoe	373
Of Paints and Painting, The. A. H. Church. Second Edition	185
Of the Carbon Compounds or Organic Chemistry. V. von Richter. Translated by Edgar F. Smith	185
Of the Organic Dyestuffs. Nietzki, Collin and Richard- son	1040
Coal-Tar Colours. A Dictionary of the. G. H. Hurst	374
Colours, A Dictionary of the Coal-Tar. G. H. Hurst	374
Practical Manual on Printers'. G. H. Hurst	1041
Commercial Organic Analysis. Second Edition. Vol. III., Part II. (A. H. Allen)	947
Destructive Distillation, A Manualette on. E. J. Mills	1041
Dictionary of Chemistry, Watts'. Revised and Re-Written by H. Foster Morley and M. M. Pattison Muir. Vol. III. Of the Coal-Tar Colours. G. H. Hurst	552
Distillation, A Manualette on Destructive. (E. J. Mills)	1041
Dyestuffs, Chemistry of the Organic. Nietzki, Collin, and Richardson	1040
Explosives and Ordnance Material. S. H. Emmens	65
And Their Power. Berthelot. Translated by C. N. Hake and W. Macnab	947
Farmyard Manure, Its Nature, Composition and Treatment. C. M. Aikman	1040
Fette und Wacharten, Analyse der. R. Benedikt	65
Fuels, Solid, Liquid, and Gaseous. Their Analysis and Valua- tion. H. J. Phillips	456
Gas Works, Their Construction and Arrangement, and the Manufacture and Distribution of Coal-Gas. Originally written by S. Hughes. Re-written by W. Richards. Eighth Edition, Enlarged and Revised	465

	PAGE
Gold, The Jeweller's Assistant in the Art of Working in. G. E. Gee	1039
Handwörterbuch der Pharmacie, von A. Brestowski	275, 374, 611
Handy Book for Brewers, A. H. E. Wright	1040
Heat and Light, Lessons in. Jones	782
Hydrocarbons and their Derivatives, The Chemistry of the. Roscoe and Schorlemmer	373
Jahrbuch der Chemie. R. Meyer	948
Technisch-Chemisches. von R. Biedermann	185
Jahresbericht über die Leistungen der Chemischen Tech- nologie. F. Fischer	947
Jeweller's Assistant in the Art of Working in Gold, The. G. E. Gee	1039
Kurzes Lehrbuch der Analytischen Chemie, von Miller and von Kiliani	65
Lessons in Elementary Chemistry. Sir Henry E. Roscoe	373
In Heat and Light. Jones	782
Manual of Chemical Technology. R. von Wagner. Translated by W. Crookes	184
Of Qualitative Blow-Pipe Analysis and Determinative Mineralogy. F. M. Endlich	1040
Manure, Farmyard; its Nature, Composition, and Treatment. C. M. Aikman	1040
Material Medica, Modern. Helbing	782
Mineralogy, Manual of Determinative. F. M. Endlich	1040
Systematic. T. Sterry Hunt	185
Oils, A Practical Manual on Printers'. G. H. Hurst	1041
Ordnance Material, Explosives and. S. H. Emmens	65
Paints and Painting, The Chemistry of. A. H. Church. Second Edition	185
Pharmacie, Handwörterbuch der. von A. Brestowski	275, 374, 611, 782
Pharmacopœia, The Extra. Martindale and Westcott	781
Phosphates of America, The. F. Wyatt. Second Edition	184
Pottasche-Fabrikation, Taschenbuch für. G. Lunge	946
Printers' Colours, Oils and Varnishes, A Practical Manual on. G. H. Hurst	1041
Reactionen. Von F. A. Plückiger	275
Silk Dyeing, Printing, and Finishing. G. H. Hurst	374
Soda-Fabrikation, Taschenbuch für. G. Lunge	946
Sulfosäuren der Beiden Naphthylamine und der beiden Naphthole, Die. Tauber	782
Tannins, The. Vol. I. H. Trimble	275
Taschenbuch für Soda, Pottasche, und Ammoniak-Fabrika- tion. G. Lunge	946
Technisch-Chemisches Jahrbuch, Von R. Biedermann	185
Technology, Manual of Chemical. R. von Wagner. Translated by W. Crookes	184
Text-Book on the Science of Brewing. E. R. Moritz and G. H. Morris	66
Varnishes, a Practical Manual on Printers'. G. H. Hurst	1041
Watts' Dictionary of Chemistry. Revised and Re-Written by H. Foster Morley and M. M. Pattison Muir. Vol. III.	552
Zeitschrift für Anorganische Chemie. G. Kruss	374

EYRE and SPOTTISWOODE,
East Harding Street, London, E.C.

LIST OF COUNCIL AND OFFICERS.

President.

Prof. J. Emerson Reynolds, M.D., F.R.S., 70, Morehampton Road, Dublin.

Vice-Presidents.

Sir Lowthian Bell, Bart., F.R.S., Rounton Grange, Northallerton.

Wm. Crowder, 271, Evering Road, Upper Clapton, E.

James Duncan, 9, Mining Lane, London, E.C.

Dr. John Evans, F.R.S., Nash Mills, Hemel Hempstead, Herts.

David Howard, Rectory Manor, Walthamstow, Essex.

S. H. Johnson, Warren Hill House, Loughton, Essex.

Ludwig Mond, F.R.S., 20, Avenue Road, Regent's Park, N.W.

Dr. Hugo Müller, F.R.S., 13, Park Square East, Regent's Park, N.W.

H. E. R. Newlands, 27, Mining Lane, London, E.C.

J. C. Stevenson, M.P., 33, Devonshire Place, London, W.

A. Norman Tate, Hackins Hey, Liverpool.

Sir John Turney, Springfield, Alexandra Park, Nottingham.

Ordinary Members of Council.

A. H. Allen, Sydenham Cottage, Park Lane, Sheffield.

Arthur Boake, Southwood Lawn, Highgate, N.

Jno. Calderwood, Gowanlea, Spencer Park, Wandsworth, S.W.

Chas. Dreyfus, Clayton, Manchester.

H. Grimshaw, Thornton View, Clayton, Manchester.

Prof. R. Meldola, F.R.S., 6, Brunswick Square, London, W.C.

E. K. Muspratt, Seaforth Hall, near Liverpool.

T. L. Patterson, Messrs. J. Walker & Co., Greenock, N.B.

Boverton Redwood, 4, Bishopsgate Street Within, London, E.C.

Jno. Spiller, 2, St. Mary's Road, Canonbury, N.

T. W. Stuart, 15, Windsor Terrace, Newcastle-on Tyne.

Wm. Thorp, B.Sc., 24, Crouch Hall Road, Crouch End, N.

Ex-officio Members of Council.

Thos. Tyrer, Stirling Chemical Works, Stratford, E.

John Heron, St. John's Villas, Worpole Road, Wimbledon.

H. Brunner, Holly Mount, Huyton, Liverpool.

Dr. Chas. A. Kohn, University College, Liverpool.

Ivan Levinstein, 21, Minshull Street, Manchester.

J. Carter Bell, Bank House, Higher Broughton, Manchester.

John Pattinson, 75, The Side, Newcastle-on Tyne.

Dr. J. T. Dunn, The School, Gateshead-on Tyne.

E. C. C. Stanford, Glenwood, Dalmeir, N.B.

Dr. G. G. Henderson, Chemical Laboratory, The University, Glasgow.

L. Archbutt, 11, Charnwood Street, Derby.

R. Lloyd Whiteley, University College, Nottingham.

Sir James Kitson, Bart., Gledhow Hall, Leeds.

H. R. Procter, Yorkshire College, Leeds.

Honorary Treasurer.

E. Rider Cook, East London Soap Works, Bow, E.

Honorary Foreign Secretary.

Dr. F. Hurter, Holly Lodge, Cressington Park, Liverpool.

General Secretary.

Chas. G. Cresswell, Palace Chambers, Westminster, S.W.

Editor.

Watson Smith, University College, London, W.C.

LIST OF MEMBERS.

A

- Abbott, John, Braemar House, Lancaster Gate, Hyde Park, W.
 Abel, Sir F. A., 10, Cadogan Place, London, SW.
 Abraham, A. C., Stanley Rock, St. George's Mount, New Brighton (Journals); and 87, Bold Street, Liverpool.
 Acland, Sir H. W., Bart., Radcliffe Library, Oxford.
 Adam, A., Learmouth, Kestatrig, Newton Street, Greenock, N.B.
 Adam, J. B., 172, Leith Walk, Edinburgh.
 Adams, M. A., Ashford Road, Maidstone, Kent.
 Adams, J. W., 74, Oxford Street, Regent Road, Salford, Manchester.
 Adeock, S. R., Minas de Rio Tinto, Provincia de Huelva, Spain.
 Addie, J., Langloan Ironworks, Coatbridge, N.B.
 Adkins, H., Ley Hill, Northfield, near Birmingham.
 Adriaens, John S., 2, West 36th Street, New York City, U.S.A.
 Affleck, Dr. J., Mill House, Woolton, near Liverpool.
 Aikman, Charles M., 183, St. Vincent Street, Glasgow.
 Aitken, Dr. A. P., 57, Great King Street, Edinburgh.
 Aitken, J. B., Gerard's Fold Chemical Works, Widnes.
 Akitt, Thomas, 3, Victoria Road, Lenzie, N.B.
 Albright, G. S., The Elms, Park Road, Edgbaston.
 Albright, W. A., Mariemont, Birmingham.
 Aleock, Jno. W., Central Brewery, Mott Street, Birmingham.
 Aldrick, Edwin John, 26, Alpha Road, West Ferry Road, Millwall, E.
 Alexander, J., Dalziel, Dechmont, Cambuslang, near Glasgow.
 Alexander, W. T., 20, Booth Street, Moseley Street, Manchester; and Cumnock Bank, Victoria Crescent, Eccles.
 Allan, F. H. Tielke, Portobello House, Wakefield.
 Allan, Jno., 3, Ludgate Circus Buildings, London, E.C.
 Aldred, C. H., 6, Heavitree Road, Plumstead Common, Kent.
 Allen, A. H., Sydenham Cottage, Park Lane, Sheffield.
 Allen, Edw. W., Dover Mills, Glossop, Derbyshire.
 Allen, G. J., Ivy House, Bolton Road, Pendleton, Manchester.
 Allen, J., 164, Upper North Street, Poplar, London, E.
 Allen, R. L., Roselagh, Heaton Chapel, near Stockport.
 Allen, Walter S., 13, Beacon St., Boston, Mass., U.S.A.
 Allen, Wm., Evenley Hall, Brackley, North Hants.
 Allen, Wm. N., 2, Chestnut Street, Philadelphia, Pa., U.S.A.
 Allhusen, A., Gateshead-on-Tyne.
 Allibon, G. H., Mewburn, Litherland Park, near Liverpool.
 Elliott, J. B. Messrs. Manlove, Elliott, and Co. Ltd., Nottingham.
 Alpiari, Agop, Smyrna, Asia Minor.
 Alsherg, M. (Sondheim, Alsherg, & Co.), P.O. Box 2137, New York, U.S.A.
 Anderson, Eugene E. J., Gasworks, Maryhill, by Glasgow.
 Anderson, Geo. B., Victoria Square, Felling-on-Tyne.
 Anderson, John, c/o The Alkaline Reduction Syndicate, Ltd., Hobburn-on-Tyne.
 Anderson, J. M. T., Explosives Co. Ltd., Stowmarket, Suffolk.
 Anderson, Robt. T. R., 618, Gallowgate Street, Glasgow.
 Anderson, Wm. Francis, 11, Montague Road, Dalston, N.E.
 Anderton, G. H., Howendyke, Howden, Yorks.
 Andrews, C. W., Mass. Inst. of Technology, Boston, Mass., U.S.A.
 Angell, J., 6, Beconsfield, Derby Road, Fallowfield, Manchester.
 Angus, James, Thorncliffe Collieries, Chapelton, Sheffield.
 Annandale, J. H., Polton, Midlothian, N.B.
 Annison, R. H., 16, Water Lane, Tower Street, London, E.C.
 Ansell, G., 45, Courtfield Road, South Kensington, S.W.
 Ansell, T. C., Kearsley Cottage, Farnworth, Bolton.
 Archbold, Dr. George, U.S. Navy Yard; and (Journals) 1224, B. Street, S.W., Washington, D.C., U.S.A.
 Archbutt, L., 11, Charnwood Street, Derby.
 Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C.
 Armstrong, Rt. Hon. Lord, Newcastle-upon-Tyne.
 Arrol, Jas., jun., João Branco, Marahu, Bahia, Brazil; and (subs.) 8, Fir Park Terrace, Dennistoun, Glasgow.
 Aron, S. B. Asher, 44, Maryland Road, Maida Vale, W.
 Aspland, Wm. Gilbert, Palmer House, Torrington, North Devon.
 Ashton-Bost, W. D., Cartvale Chemical Works, Paisley, N.B.
 Ashwell, H., Langley Dale, Grove Avenue, Southley Street, Nottingham.
 Ashwell, J. H., Woodthorpe Grange, Sherwood, Nottingham.
 Ashwell, Jno. R., 114, Waterloo Crescent, Nottingham.
 Ashworth L., Sunny Lea, St. Anne's-on-Sea, Lancashire.
 Atcherley, Dr. R. J.
 Atkins, C. E., East Ham House, East Ham, Essex.
 Atkinson, A. J., 41, Loudoun Square, Cardiff.
 Atkinson, R. W., 44, Loudoun Square, Cardiff.
 Attfield, Dr. J., Ashlands, Watford, Hertfordshire.
 Auer, H., Appleton Lodge, near Widnes.
 Auerbach, Dr. C. G., 25, Friesenheimer Strasse, Ludwigshafen a/ Rhein, Germany.
 Austen, Prof. Peter T., 569, Vernon Avenue, Long Island City, N.Y., U.S.A.
 Aykroyd, H. E., Ashwell, Toller Lane, Bradford, Yorks.

B

- Babington, Percyval, Astyra Mining Co., Dardanelles *viz* Constantinople.
 Bache, Arthur E., 81, Elswick Road, Lewisham, S.E.
 Bachmann, Dr. Irvin A., Georgia Chemical Works, Augusta, Georgia, U.S.A.
 Bailey, Edwin M., Millbank Cottage, Uphall, N.B.
 Bailey, Dr. G. H., Owens College, Manchester.
 Bailey, Richard D., City Brewery, Gloucester.
 Bailey, Thos., 25, High Street, Hull.
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool.
 Bailey, W. H., Albion Works, Salford, Manchester.
 Bailey, Walter P., 8, South Park, Ilford, Essex.

 Watson, Chas., Walsden Chemical Works, near Todmorden.
 Watson, D., 244, Great Clowes Street, Manchester.
 Watson, Eric E., Schulstrasse 288, Clausthal a/Harz, Germany.
 Watson, G., jun., 16, East Nelson Street, Whitevale, Glasgow.
 Watson, Geo. P., Elm Lodge, Halliwell Lane, Cheetham Hill, Manchester.
 Watson, Harry F., Erie, Pa., U.S.A.
 Watson, Jno C., c/o Daniel Lee & Co., Castleton, Manchester.
 Watson, Jno., Cement Works, Gateshead-on-Tyne.
 Watson, Jno., Laboratory, Newcastle Chemical Co., Gateshead-on-Tyne.
 Watson, Jno., 8, Newman Street, Victoria Docks, E.
 Watson, W. H., Laboratory, The Folds, Bolton.
 Watt, A., 89, Hartington Road, Sefton Park, Liverpool.
 Watts, A. J., 130, Caixa, Pernambuco, Brazil.
 Watts, Chas. W., Corporation Gasworks, Belfast.
 Watts, Sydney E., Tyne Brewery, Newcastle-on-Tyne.
 Webb, Saml. G., c/o United Alkali Co., Ltd., Pilkington Works, Widnes.
 Webb, Wm. Hubert, Randalstown, co. Antrim, Ireland.
 Webber, Geo. W., Oswald Hill, Broomhill Drive, Partick, Glasgow.
 Weber, Carl Otto, 1, Rectory Road, Crumpsall, Manchester.
 Webster, C. S. Stanford, Malvern House, Redland, Bristol.
 Webster, Wm., jun., The Grove, Belmont Hill, Lee, S.E.
 Weed, Hy. T., 82, Robinson Street, Allegheny, Penn., U.S.A.
 Weightman, John F., c/o Powers & Weightman, Philadelphia, Pa., U.S.A.
 Weir, Surgeon-Major P. A., Residency, Nepal, via Bombay, India.
 Weldon, Ernest.
 Wells, G. I. J., Kinderton Lodge, Middlewich, Cheshire.
 Wells, Jas. Gray, 26a, St. Paul's Street West, Burton-on-Trent.
 Welsh, Jas., Kinder Printworks, Hayfield, near Stockport.
 Wells, John, 33, Northampton Square, Clerkenwell, E.C.
 Welsh, Thos. L., 3, Prince's Gardens, Downhill, Glasgow.
 Welsh, W., Holt Town, Manchester.
 Werner, Emil A., 5, Church Avenue, Rathmines, Dublin.
 Wessel, Carl, Bernburg, Anhalt, Germany.
 Westmoreland, J. W., 25, Park Square, Leeds.
 Weston, Wm., H.M. Dockyard, Portsmouth.

- Wetter, Jasper, 433, Strand, London, W.C.
 Wetzel, H. A., Box 470, Detroit, Michigan, U.S.A.
 Whalley, L. J. de, 26, Park Place, Greenwich, S.E.
 Wheeler, Wm. E., Cumberland House, Meynell Road, South Hackney, N.E.
 Whelan, Edwin J., Star Chemical Works, Wandsworth Bridge Road, Fulham, S.W.
 Whewell, Wm., Irwell House, Duncers Lane, Radcliffe, near Manchester.
 Whiffen, T., Lombard Road, Battersea, London, S.W.
 Whiffen, T., jun., Lombard Road, Battersea, London, S.W.
 Whiffen, W. G., Lombard Road, Battersea, London, S.W.
 Whitaker, H. L., Condong Sugar Mill, Tweed River, New South Wales.
 Whitaker, Thorp, Messrs. E. Ripley & Sons, Bradford, Yorks.
 White, A., Horton Field, West Drayton, Middlesex.
 White, A. D., Avenue House, West Drayton, Middlesex.
 White, Henry, 8, Brown Street, Mashboro', Rotherham.
 White, Jos. W., Halebank, near Widnes.
 White, J. Campbell, 7, West George Street, Glasgow.
 White, P. T., Castle Street, Saffron Hill, London, E.C.
 White, W. H., Killingworth House, Killingworth, Newcastle-on-Tyne.
 Whitehouse, Enoch, 513, Coventry Road, Smallheath, Birmingham.
 Whitelaw, T. N., 87, Sydney Street, Glasgow.
 Whiteley, Geo., Victoria Lead Works, Burdett Road, Limehouse, E.
 Whiteley, R. Lloyd, University College, Nottingham: Journals to 13, Bowers Avenue, Woodborough Road, Nottingham.
 Whittaker, C. J., Globe Chemical Works, Church, near Accrington.
 Whittaker, Thos., 22, Delaunays Road, Higher Crumpsall, Manchester.
 Whowell, F., Carr Bank, Tottington, Bury, Lancashire.
 Wickens, B. Foster, 183, Queen Street, Cheapside, London, E.C.
 Wigg, G. L., Runcorn.
 Wiggin, W. W., Wiggin Street, Birmingham Heath, Birmingham.
 Wightman, C., 1, Fenchurch Avenue, London, E.C.
 Wild, Eugene.
 Wilde, T., Penclawdd, near Swansea.
 Wilding, Jas., jun., 266, Burdett Road, E.
 Wiley, M. W., Billsdale House, York Road, West Hartlepool.
 Wilkie, T. M., Nobel Co.'s Works, Stevenston, Ayrshire N.B.
 Wilkin, Walter H., Appold Street, Finsbury, E.C.
 Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks.
 Will, W. Watson, The Lanrels, Galveston Road, Putney, S.W.
 Williams, D., c/o United Alkali Co., Ltd., Gerard's Bridge Works, St. Helens.
 Williams, Edward, Polly Farm, Warrington.
 Williams, Geo. G., 624, South 24th Street, Philadelphia, Pa., U.S.A.
 Williams, Henry J., c/o Davenport and Williams, 161, Tremont Street, Boston, Mass., U.S.A.
 Williams, Percy B., Felbrigg, The Bank, Highgate, N.
 Williams, Prof. W. Carleton, Firth College, and 33, Bromsgrove Road, Sheffield.
 Williams, Rowland, 28, Pall Mall, Manchester.
 Williams, Rupert G., Albion Mills, Heywood, near Manchester.
 Williams, Seward W., 487, Central Avenue, East Orange, Mass., U.S.A.
 Williams, T., A., Queen Insurance Buildings, 10, Dale Street, Liverpool.
 Williams, T. Howell, 10, Ascham Street, Kentish Town, N.W.
 Williams, W. Collingwood, 44, Mulgrave Street, Liverpool.
 Williams, W. J., 1412, Van Buren Street, Wilmington, Del., U.S.A.
 Williamson, Robt., Cleveland Chemical Works, Middlesbrough.
 Wills, G. S. V., Southwood, Croham Road, South Croydon.
 Wills, J. Lainson, 206, Albert Street, Ottawa, Canada.
 Wilson, A., The Firs, Norton, near Stourbridge.
 Wilson, Alex. P., 56, Bridge Street, Birkenhead.
 Wilson, Alf., c/o Messrs. J. and E. Sturge, 18, Wheeley's Lane, Birmingham.
 Wilson, Anthony W., 20, Westcott Street, Hull.
 Wilson, Cecil H., 656, Grimsthorpe Road, Sheffield.
 Wilson, C. J., 19, Little Queen Street, Westminster, S.W.
 Wilson, David, jun., Carbeth, Kilmearn, by Glasgow.
 Wilson, Frank, The Brewery, Castle Street, Long Acre, London, W.C.
 Wilson, Gordon, jun., Crestone, Saguache Co., Colorado, U.S.A.
 Wilson, G. E., The Chemical Works, Oldbury, near Birmingham.
 Wilson, Jno. A., South 20th and Mary Streets, Pittsburgh, Pa., U.S.A.
 Wilson, Jno. Ed., Wyddrington, Edgbaston, Birmingham.
 Wilson, Jno., 28, Crosby Road, Romford Road, Stratford, E.
 Wilson, Jos. A., Crossfields, Tottington, near Bury, Lancashire.
 Wilson, J. H., 6, Fenchurch Buildings, E.C.
 Wilson, J. Millar, Ridley Park, Delaware Co., Pa., U.S.A.
 Wilson, R. H., Egglescliffe, Yarm-on-Tees.
 Wilson, Wesley Wm., James' Gate Brewery, Dublin.
 Wilson, Dr. W. H., 15, Perham Road, West Kensington, W.
 Wilson, Wm. Robt., 110, Long Acre, London, W.C.
 Wilson, W. W., Chirnside Villa, Droydsden, Manchester.
 Wilson, Wm., Journals to Delhi, India; Subscription c/o Clark, Wilson, & Co., 155, Fenchurch Street, E.C.
 Wilton, Geo., Tar Works, Beckton, E.
 Wilton, Jno., Clydesdale, Norwich Road, Forest Gate, Essex.
 Wilton, Thos., Winsor House, Beckton, E.
 Windus, W., 15, Vyvyan Terrace, Clifton, Bristol.
 Wingham, A., 3, Villa Road, Brixton, S.W.
 Winsor, P. J., Wyck House, Bebington, Cheshire.
 Winsloe, H., Messrs. Tennant & Co., 49, Faulkner Street, Manchester.
 Winstone, A. B., 7, Gray's Inn Square, London, W.C.
 Winstone, E. H., 2, Victoria Mansions, Victoria Street, London, S.W.
 Wire, A. P., 1, Seaton Villas, Birkbeck Road, Leytonstone, E.
 Wishart, Jno., 39, St. Vincent Place, Glasgow.
 Witt, Dr. Otto N. E., Lindénallee 33, Westend, bei Berlin.
 Wolfenden, S., Wellington Terrace, Cowley Hill, St. Helens.
 Wollheim, Hugo, 21, Ridgway Place, Wimbledon, Surrey.
 Womersley, P. B., Lynmead, Wanstead, Essex.
 Wonfor, Wm. Jos., Lake View, Bessbrook, Co. Armagh.
 Wood, Ebenezer, Stephenson Street, Canning Town, E.
 Wood, E. T., Brinscall, Chorley, Lancashire.
 Wood, Jas., Stockwith-on-Trent, Gainsborough.
 Wood, Joseph, Brinscall, near Chorley, Lancashire.
 Wood, J. Turney, Hound Road, West Bridgeford, Nottingham.
 Wood, Milton R., Wyandotte, Mich., U.S.A.
 Wood, Robt. B., Dalquharn Works, Renton, N.B.
 Wood, Wm., 128, Chaussée de Turnhout, Antwerp, Belgium.
 Wood, W. C., Rosshead, Alexandria, Dumbartonshire.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—VOL. XI.]

JANUARY 30, 1892.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Dunean.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnsen.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimsshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	F. Hurter, Ph.D.
L. Archbutt.	C. C. Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	B. E. R. Newlands.
E. Rider Cook.	John Pattinson.
W. Y. Dent.	W. H. Perkin, Ph.D., F.R.S.
Chas. Dreyfus, Ph.D.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	A. Norman Tate.
David Howard.	Wm. Thorp.
Prof. J. J. Hummel.	Thomas Tyrer.
Prof. A. K. Huntington.	

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	J. Walter Leather, } XV. Ph.D. }
H. Auer VII.	F. H. Leeds III., XXI.
T. L. Bailey, Ph.D. Gen.Chem.	A. Liebmarn, Ph.D. { IV., VI., XX. }
G. H. Beckett .. V., VI., VII.	A. R. Ling IV., XVI.
D. Bendix III.	D. A. Louis XV.
E. Bentz IV., V., VI.	W. Macnab XXII.
Jos. Bernays, M.I.C.E. I.	K. E. Markel, Ph.D. ... XII.
E. J. Beran V., XIX.	A. K. Miller, Ph.D. ... III., IV.
Bertram Bount. { IX., XI., XII., XIII. }	N. H. J. Miller, Ph.D. XV.
Arthur G. Bloxam XIV., XV.	J. M. H. Munro, D.Sc. XV.
C. H. Bothamley XXI.	H. S. Pattinson, Ph.D. VII., X.
E. G. Clayton ... { IX., XIII., XVIII. }	H. T. Penter- } XVI., XVII. mann. }
V. Cornish ... VIII., IX., XIII.	F. W. Renaut ... Patent Lists
C. F. Cross ... V., XII., XIX.	H. Schlichter, Ph.D. ... V., XV
Oswald Hamilton ... I.	Edward Simpson I.
P. J. Hartog, B.Sc. Gen. Chem.	A. L. Stern, B.Sc. XVII.
Prof. D. E. Jones, B.Sc. XI.	D. A. Sutherland ... II., III.
W. E. Kay VI.	N. W. Tchaykovsky. B.A. Gen Chem. (Russian Lit.)
A. J. King, B.Sc. ... VI., XVI.	Bertram Thomas XI.
F. S. Kipping, } II. and D.Sc. } Gen. Chem.	Eustace Thomas XI.
Chas. A. Kohn, } Gen. Chem. Ph.D. }	H. K. Tompkins, B.Sc. X.
L. de Koningh XVIII., XXIII.	V. H. Veley, M.A. Gen. Chem.
T. A. Lawson, Ph.D. ... IV.	A. Wingham X.

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, January, February, and April 1886, and February 1889. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 22nd JANUARY 1892.

Bookman, S., Mittel-strasse 24, 1, Berlin, chemical student.
Breidahl, Harold T. W., Federal Distillery, Port Melbourne, Victoria, manager.

Buckley, Edwin, Beaver Park, Did-bury, Manchester, chemical student.

Butterfield, W. J. A., 10, Tressillian Crescent, St. John's, S.E., analytical chemist.

Crawley, Arthur H., c/o Elmore's Patent Copper Depositing Co., Lim., Pontefract Road, Hunslet, Leeds, analytical chemist.

Davies, W. E., Beaumaris, R.S.O., North Wales, quarry and lime works manager.

Dobb, Thos., Audrey Cottage, Union Road, Sharrow, Sheffield, pharmaceutical chemist.

Fleming, Arnold, Britannia Pottery, 136, Glebe Street, Glasgow, potter.

Gilbard, Francis, The Laboratory, 17, Great Tower Street, E.C., analytical chemist.

Haigh, Ben, 21, Cavendish Road, Leeds, dyer and dye-wood extract maker.

Hill, Sydney, 11, Salisbury Street, The Park, Hull, analyst.

Hinshelwood, Thos., Glasgow Oil and Paint Works, Glenpark Street, Glasgow, oil refiner.

Kaufmann, Dr. Herbert M., 1325, Franklin Street, Philadelphia, Pa., U.S.A.

Kinnicutt, Prof. Leonard P., Worcester Polytechnic Institute, Worcester, Mass., U.S.A., professor of chemistry.

Pettigrew, Robt., 21, Titchborne Street, Edgware Road, W., electro-chemist.

Potts, Jos. T., Price's Works, Bromboro' Pool, near Birkenshead, chemist.

Robertson, G. H., 30, Hemstall Road, West Hampstead, N.W., electro-chemist.

Shanks, Archibald, Bridgend Mills, Dalry, Ayrshire, N.B., chemist.

Sykes, Jas., 76, Lockwood Road, Huddersfield, analytical chemist.

Warden, Jno. B., c/o B. Kitto, 30-31, St. Swithin's Lane, E.C., analytical chemist.

Watson, Geo. P., Elm Lodge, Halliwell Lane, Cheetham Hill, Manchester, printworks chemist.

Weed, Henry T., 82, Robinson Street, Allegheny, Pa., U.S.A., teacher of analytical chemistry.

CHANGES OF ADDRESS.

Adrianne, Jno. S., 1, o Huntingdon; 2, West 36th Street, New York City, U.S.A.

Benger, F. Baden, 1, o Manchester; The Grange, Knutsford, Cheshire.

Bird, H., 1, o Devonport; South Down House, South Down, Plymouth.

Brasher, F. W., 1, o 1; 8, Wyatt Road, Forest Gate, E.

Brunner, J. F. L., 1, o Warrington Old Hall; The Hollies, Hartford, Cheshire.

Budden, E. R., 1, o Hampstead; 11, Farnival Street, Holborn, E.C.

Burn-Murdoch, J. V., 1, o Gravesend; c/o Capt. P. R. Burn-Murdoch, Pembroke Dock, South Wales.

Collins, H. S., 1, o Finsbury; c/o General Apothecaries Co., 49, Berners Street, W.

Cooper, H. P., 1, o 4; 64, Foxham Road, Upper Holloway, N.

Davis, A. R., 1, o Heaton Norris; Dunowen, Knutsford, Cheshire.

Dvorkovitz, P., 1, o Finsbury Park; Fernwood, North Hill, Highgate, N.

Eastwick, J. H., 1, o Norristown; Mellon Street, above Margaretta, East Liberty, Pittsburgh, Pa., U.S.A.

Emmens, S. H., 1, o New Stanton; Youngwood, Westmoreland Co., Pa., U.S.A.

Ford, J. S., 1, o Abbotsford Park; Abbey Brewery, Edinburgh.

Goldschmidt, Dr. S. A., 1, o Jay Street; 43-51, Sedgwick Street, Brooklyn, N.Y., U.S.A.

Gregory, W. J., 1, o St. Thomas Street; 1, St. John's Terrace, Weymouth.

Hall, J. A., 1, o 128; 108, Lloyd Street, Greenheys, Manchester.

Herman, D., 1, o West Park; St. Ann's, St. Helens.

Heslop, Jos. 1, o Jarrow; 110, Rye Hill, Newcastle-on-Tyne.

Horrocks, S., 1, o Prince's Park; 41, Parkfield Road, Sefton Park, Liverpool.

Humphries, J., 1, o Edward Street; c/o Humphries and Co., Adolphus Street, Bradford, Yorks.

Ingle, Harry, Journals to Jägerstrasse 7, IV., München, Bavaria.

Johnston, W. G., 1, o Hoboken; c/o A. Burns Glen, 8, Great Winchester Street, E.C.

Kershaw, J. B. C., 1, o Streatham Hill; University Hall, Gordon Square, W.C.

Kunheim, Dr. H., 1, o Lindenstrasse; 32, Doratheenstrasse, Berlin.

Lagerwall, Dr. Ivar, 1, o St. Petersburg; Rodhusrätten, Stockholm, Sweden.

Leete, Jos., 1, o Teoley Street; 19-25, Bermondsey St., S.E.

Lindemann, G., 1, o Altona; Langerreihe 48, II., rechts, St. Pauli, Hamburg.

Ling, A. R., 1, o Wandsworth; Brooklands, Thames Ditton, Surrey.

Liversedge, A. J., 1, o London; c/o Mirrlees, Watson, and Yaryan Co., Ltd., 45, Scotland Street, Glasgow.

Lodge, Edw., 1, o 35; 27, Cowcliffe Hill, Huddersfield.

Lunn, C., 1, o Fenay Bridge; Slantgate, Kirkburton, near Huddersfield.

Luthy, Otto, 1, o Philadelphia; c/o American Alumina Co., Barberton, Ohio, U.S.A.

Mambes, P., 1, o Rue du Plat; 3, Rue Sala, Lyon, France.

McDougall, A., 1, o Greenheys; Fallowfield House, Fallowfield, Manchester.

Meyer, Max E., 1, o Sutton; 8, Duchess Street, Portland Place, W.

Miller, Dr. A. K., 1, o Hammersmith; Ardwick Brewery, Manchester.

Nichols, W. H., 1 o 11: 45—17 Cedar Street, New York City, U.S.A.

Petty, A., 1 o Stamford Hill; 33, Clapton Common, E.

Pilkington, G., Journals to Laboratory, 28, Pall Mall, Manchester.

Quincke, Dr. F., 1 o London; Chemische Fabrik Rhenania, Stolbergh bei Aachen, Germany.

Ramsay, Wm., 1 o Liverpool; Chemical Laboratory, University College of Wales, Aberystwith.

Reid, W. G., 1 o Kimberley; Soap Works, Beaconsfield Diamond Fields, South Africa.

Richards, Edgar, 1 o Washington; 113, East 30th Street, New York, U.S.A.

Richardson, C. T., 1 o Newcastle; 27, Jewin Crescent, Cripplegate, E.C.

Sankey, C. H.; all communications to Hillsboro' Lodge, Dulwich Grove, North Dulwich, S.E.

Schellhaas, H., 1 o 54; 38, Navigation Road, Northwich.

Scott, Ernest G., 1 o Bebbington; Woodcliffe, Burgess Hill, Hampstead, N.W.

Serutton, W. J., 1 o Nevada; Lake Valley, New Mexico, U.S.A.

Semet, L., 1 o Rue du Prince Albert; 217, Chaussée de Vleurgat, Brussels.

Smith, A. J., 1 o Catherine Street; 81, Page Hall Road, Fir Vale, Sheffield.

Smith, R. Watson, 1 o Uphall; Young's Oil Co., Lim., Chemical Works, Bathgate, N.B.

Solvay, A., 1 o Boitsfort; 25, Rue de Prince Albert, Brussels.

Solvay, E., 1 o Rue du Prince Albert; 13, Rue des Champs Elysées, Brussels.

Stevenson, J. C., M.P., 1 o South Shields; 33, Devonshire Place, W.

Stevenson, J. S., 1 o South Shields; 33, Devonshire Place, W.

Taylor, Jno., 1 o Belgrave Pharmacy; 15, Lucius Street, Torquay.

Thomson, Dr. And., 1 o 7; 10, Pitenullen Terrace, Perth.

Tomlinson, G. G., 1 o Widnes; c/o W. B. Kay, 16, Halton Road, Luncorn.

Tompkins, H. K., 1 o Pimlico; 11, Promenade, Bromley, Kent.

Trimnell, C. H., 1 o New Malden; Elmhurst, Malden, Surrey.

Voecker, E. W., 1 o Salisbury Square; 22, Tudor St., E.C.

Walker, Alex., 1 o Irvine Chemical Co.; Alex. Walker & Co., Alkali Works, Irvine, N.B.

Waterhouse, Robt., 1 o Sheffield; Villa Bejach, Jena (in Thuringen), Germany.

Wilding, Jas., jun., 1 o Lancashire; 266, Bardett Road, E.

Young, Jno., 1 o Bellhaven Terrace; 2, Montague Terrace, Kelvinside, Glasgow.

EXCHANGE LIST.

Fischer, Dr. F., 1 o Hanover; 26, Wilhelm Weber Strasse, Göttingen, Germany.

Deaths.

Heisch, Chas., 79, Mark Lane, E.C.

Perkin, T. D., Greenford Green, Harrow.

Powell, W. A., Maison Marie Louise, Hyeres (Var), France.

Towns, Wm., Irwell Lane, Runcorn.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Vice-Chairman: W. Crowder.

Committee:

C. F. Cross.

Meeting held Friday, December 4th, 1891.

MR. IVAN LEVINSTEIN IN THE CHAIR.

THE PURIFICATION OF SEWAGE BY PRECIPITATION.

BY J. BARROW.

THE origin of this paper is from some experimental work which I was requested to undertake, as to the action on sewage of a new precipitant, technically known as "Clarine." The material is in the form of a solution which consists mainly of a very basic perchloride of iron, absolutely free from ferrous salts. That is to say, it is a ferric chloride, supersaturated with ferric hydrate.

I have not made a sufficiently minute chemical examination of the iron compound contained to be able to state whether it is an oxychloride or not, but such is probably the case.

I have made a large number of experiments, both quantitative and qualitative, on many samples of sewage and works effluents of various descriptions, including among others the sewages of Salford, Pendleton, Moston, Newton Heath, Failsworth, Gorton, Clayton, and Acerington, effluents from bleach works, paper works, dye works, sizing and finishing works, jail washings from the Manchester Corporation Cleansing Department, and also the water from the Manchester Ship Canal Docks.

I may make the following observations on the action of Clarine:—

1. As a general rule what I should call the worst sewages are the most easily purified, that is to say, those sewages containing the most fecal or similar putrescible matter.

2. It is most essential to observe the exact condition of the sewage as to neutrality, alkalinity, or acidity before adding the precipitant. Most descriptions of sewage and effluent waters are best precipitated in a neutral solution, many are efficiently acted on in alkaline, whilst in a certain number the precipitate does not easily subside unless the sewage or effluent is acid.

3. It is almost essential to add exactly the right quantity of "Clarine," any deviation from this usually interfering with the clarification and subsidence of the precipitated matters. The quantity I found suitable to most sewages is about 15 grains per gallon, that is to say about one ton to the million gallons. This quantity I found to work admirably with Salford sewage.

4. The "Clarine" has a remarkably quick action, rendering the albuminous matters in solution insoluble, and the flocculent precipitate thus formed, as a rule subsides with great rapidity. This may be owing to the excess of iron it contains.

I will now proceed to a consideration of the numerical data bearing on the subject of the paper.

For the purposes of comparing the action of "Clarine" with that of other precipitants and processes, I have been

able to obtain figures ready to hand which are the work of Mr. Carter Bell, Dr. Burghardt, Dr. Angus Smith, Dr. Wallace, and others in relation to the "International," "Electrical," and "lime" processes. These are the only processes which can be said to be in the field for the purification of sewage.

The major part of my attention has been devoted to the analysis of effluents produced by the action of "Clarine" under varying conditions.

I will first quote, however, one special series of experiments which I made with four different methods of precipitation, viz., "lime," "ferrous sulphate," "alumino-ferric cake and lime," and "Clarine."

These experiments were performed on Salford sewage with chemically equivalent quantities of ferrous sulphate and sulphate of alumina and 15 grains per gallon of lime.

These experiments illustrate the chemical action of the processes above enumerated, as the precipitation portion of the "International" and "Electrical" systems is the addition of soluble ferrous compounds to the sewage in what I venture to say an unnecessary expensive form.

The figures which I have chosen as the best indication of the amount of noxious polluting material in sewage is the amount of albuminoid ammonia. The reasons for this we can discuss if time permits. I merely remark here, that the adoption of this figure is as fair to one process as another.

To summarise my results, the average amount of albuminoid ammonia contained in the raw sewage was 0.12 parts per 100,000, which, after treatment, was reduced as follows:—

	Parts per 100,000.
Ferrous sulphate	0.045
Alumino-ferric cake and lime	0.03
Lime	0.03
"Clarine"	0.02

The above figures give the following average percentages of purification—

	Per Cent.
Ferrous sulphate	62
Alumino-ferric cake and lime	75
Lime	75
"Clarine"	83

as indicated by the loss in albuminoid ammonia. The percentage of purification by the lime is considerably higher than is often the case, being generally about 40 per cent.

This appears certainly in favour of the last-named process. The sewage at the time was apparently in a very dilute condition, owing, no doubt, to the heavy rain we were having, but I am of opinion that with more concentrated sewage "Clarine" would remove proportionally larger amounts of noxious matter. I am proceeding with further work, which will decide this.

The following are a few results obtained from sewages of various descriptions before and after treatment with 15 grains per gallon of Clarine:—

	1891.	Free Ammonia.	Albuminoid Ammonia.	Percentage of Albuminoid Ammonia removed.
		Parts per 100,000.		Per Cent.
Sewage	Salford, 19th November	0.45	0.16
Effluent	Salford, after treatment	0.36	0.025	84
Sewage	Salford, 1st October	0.5	0.50
Effluent	Salford, after treatment	0.4	0.05	90
Sewage	Salford, 5th October	0.6	0.60
Effluent	Salford, after treatment	0.6	0.02	96
Water	Ship Canal, 17th November	0.1	0.05
Effluent	Ship Canal, after treatment	0.1	0.005	90
Sewage	Heaton Mersey, December 18 90	1.5	0.8
Effluent	Heaton Mersey, after treatment	2.00	0.15	81
Sewage	Moston Brook, 2nd December	0.2
Effluent	Moston Brook, after treatment	0.03	85

The samples taken from Heaton Mersey were taken before and after treatment on the large scale.

The following table contains a number of determinations of albuminoid ammonia contained in the effluents from the different processes under consideration.

THE COST OF SOME OF THE PROCESSES OF SEWAGE TREATMENT.

BY HARRY GRIMSHAW, F.C.S.

THE consideration of cost in relation to sewage matters is, as we all know, not only important but absolutely vital. In the case of any process otherwise fairly effective we must ascertain what the expense of working it will be, for, of course, the process may be put out of court simply on account of the prohibitive cost of working it. All studies therefore of the chemical bearings of the different methods of dealing with sewage must of necessity run concurrently with the study of the cost of those processes. Now, as many of you know, the different materials which have been used for the so-called purification of sewage are in number legion. I will just run through a few of them for the amount of chemical interest an enumeration of the names may contain. Lime has been used, chloride of lime, gas-tar, chloride of magnesia, sulphate of alumina, otherwise called aluminiferous, phosphates of lime and other phosphates, sulphate of iron, and black-ash waste. Then we have the "A, B, C" process with its alum, blood, and clay; but to the "A, B, C" they did at one time add magnesia, manganate of soda and potash, charcoal (animal and vegetable), magnesian limestone, carbon waste (from prussiate works), and coal-dust.

Coming down to recent times, there is herring brine, an extraordinary compound to my mind, and perchloride of iron. Most of these substances are what, I venture to say, most chemists would call absurdities with regard to their purifying action on sewage. I would only remark in relation to them that probably those of them I have named which are added in a liquid form are rather better than those which are added in a solid form, because they do not gratuitously add weight to the sludge which is subsequently precipitated. Very luckily for me, and for you also, in considering the question this evening, the possible processes for sewage purification appear to me to be few, and I think barrow in the previous paper enumerated almost all of them.

These processes are principally, I might say, precipitation processes, or they are processes of precipitation followed by subsequent filtration. I have thought it well this evening to leave the treatment of sewage by irrigation out of consideration for the moment, because it would have caused my address to assume an undue length had I done otherwise; and another reason is that we find as a rule that processes of irrigation are not by any means suited to towns in crowded manufacturing districts, and certainly not for the district of which Manchester may be said to be the centre. Of course that is in consequence of the very large area of land which is apparently required for the effectual treatment of sewage by irrigation. In England, as far as I can judge from the data furnished by experiments tried in various parts of the country, about 200 acres of land are required for a million gallons of sewage per day, if you are to be safe under all contingencies. It is true that in France they appear to be able to do with less land. From Paris it is reported that they have fairly successfully treated one million gallons of sewage per day on 90 acres of land. It may be that the climate of France is more suitable for irrigation systems than that of England, which, as we all know, is very continuously wet. For nearly half of the year, in consequence of the incessant rainfall, we have our land in a water-clogged condition, independent of any sewage effluent we may pour upon it. Another reason why I have not gone into the cost of irrigation is that the sewage in manufacturing towns is not at all adapted for farm irrigation. I fancy a good deal of it is much better adapted to kill grass and various kinds of vegetation than to nourish it. Yet another reason is that it is difficult to get reliable data of the cost of irrigation. Premising the incidental matters I have thus indicated, the real purpose of my paper is to present in a condensed and simplified form a comparison of the cost of some of the chemical processes which have been tried or are likely to be adopted on a large scale for the purifying of sewage. The processes between which the comparison of cost are made in my paper are mainly, as I said before, those which formed the subject of the paper of Mr. Barrow; but they will also, of course, contain references to what I might call other than chemical processes. The data on which the present study of the question of cost is based, in so far as I could possibly base it, on the results of actual working or of trials on a very large scale, and I will proceed to an examination of the cost of about six processes, which, so far as I can judge, are the only ones that appear likely to come into actual practice on a large scale. The six processes I refer to are the lime treatment, the aluminiferous process, the Barry Company's process, the electrolytic process, the international process, and the Clarine process, which last is the newest of the series and will shortly, I am informed, be put into operation on the whole of the Salford sewage. In the first place, I will call your attention to figures in connexion with—

THE LIME TREATMENT.

At this stage I think I ought to acknowledge my very great indebtedness to the report of the Salford Sewage Committee, which I think I am not far wrong in saying forms by far the largest and most significant attempt extant in this country to obtain a definite conclusion in regard to those different processes of sewage treatment, and of course in this case the figures are based on actual working of the process or on very large experiments which have been carried on at Salford. I need scarcely say that I have

checked these figures wherever possible by comparison with data from other districts. I take now the annual cost of the lime treatment as at Salford. The actual amount of sewage which I believe has been treated at Salford regularly is something like 8,000,000 gallons per day, and I have been able to obtain the figures for the treatment of that amount of sewage, so that the figures I give you first relate to the treatment of 8,000,000 gallons per day. I have summarised the figures, so that I shall not detain you by unnecessary wandering in a maze of detail. The cost of the actual lime treatment, including the cost of the lime and the labour of putting it in, is 54*l.* 10*s.* per week, which is equivalent to 2,854*l.* per annum. The pumping of the sewage costs about 36*l.* per week, which is over 1,800*l.* per annum. The manipulation of the sludge costs about 29*l.* per week, which is a little over 1,500*l.* per annum. Taken together, the sums I have mentioned give a total of 6,248*l.* per annum. Well, in order to make that figure complete—of course I hope that my way of getting at the figures will be criticised as freely as possible—in order to make that estimate complete, I have added to that what appears to me to be the expense of the sinking fund in connexion with the sewage accounts, and that I have taken the liberty of culling from a letter of Mr. Councillor Corbett, in the "Manchester Guardian," where he states that amount to be 3,626*l.* The total, therefore, of these items for the lime treatment of 8,000,000 gallons is 9,874*l.*; you may say within a shade of 10,000*l.* Now on my own account I have added to that the cost, as ascertained from the Salford figures, of filtering the effluent, which would be 1,020*l.* So that if you filtered the lime-treated sewage you would have a cost of 10,894*l.* In following these comparisons out I have calculated the foregoing figures, and the figures for the other processes, on 10,000,000 gallons per day, and increasing the cost at Salford to 10,000,000 gallons per day, I get for the lime treatment at the above rate—materials and labour and incidental cost of operations—3,567*l.*, and for filtration through sand filters, six acres and works thereto, taken on the authority of the Salford engineer, 23,500*l.* at 5 per cent. per annum, 1,275*l.*, or a total of 4,842*l.* In order to make sure that I was not deceiving myself, and to make sure that the Salford figures were not deceiving me in any way, I have looked up the report of the Bradford sewage works, where they also use the lime process, and I have obtained very exhaustive figures indeed from this report. I have obtained separately the cost of management, labour, rates, lime, coal, coke breeze and coke, oil, grease, and tallow, gas water, cotton waste, repairs to boilers and machinery, repairs to tools and implements, blacksmith and ironmonger, charge for railway siding, and miscellaneous expenses (See Table No. 2.) This appears to me to be a very exhaustive summary, and the figures given for the quantity which is purified at Bradford agree very fairly well with the Salford figures, that is, of course, without taking into consideration any question of sinking fund, because that is a matter of local arrangement, and would vary very much. Allowing for the fact that the lime is a little cheaper at Bradford, the figures given in the Bradford report agree well with those in the Salford report.

The cost of the lime and the cost of putting it in, and the cost of the filter at Salford come to 4,842*l.* for 10,000,000 gallons, and this agrees well with the figures for the Bradford lime process in 1878, viz., 4,670*l.* We next have the cost of manipulating the sludge—I have a table with regard to this which I will quote later on—at Salford from 10,000,000 gallons and taking their own 8,000,000 gallons as the basis of the calculation of the cost of manipulating the sludge it is 1,902*l.* Now in order that I may convey the figures to you more precisely, and in order that you may be able to follow me in these comparisons, I have calculated the cost per annum down into cost per million gallons per annum for precipitation, for filtration and manipulation of sludge, and then I have calculated the actual cost for one million gallons only. The cost per million gallons per annum for precipitation in Salford is 217*l.*, the cost of filtration 270*l.*, and the cost of manipulating the sludge 190*l.*, making a total of 677*l.* per million gallons per annum. That gives us an actual cost per million gallons of 37*s.* 1*d.* Now then we will take the so-called—

ALUMINO-FERRIC PROCESS.

It is really the sulphate of alumina process, because the only thing which can dignify it as "ferric" at all is the presence in it of a trace of sulphate of iron. It is really sulphate of alumina. Here again I am basing my figures on actual experiments carried on at Salford. I find that aluminoferric cake, 4,500 tons at 2*l.*, costs 9,000*l.* Then you add to that 1,600 tons of lime at 10*s.* a ton, 800*l.* Labour is put down at 1,700*l.*, depreciation and repairs 150*l.*, and sand filters, six acres and works—the same ground as before—25,500*l.* at 5 per cent., 1,275*l.*; total 12,925*l.* That gives us a cost per million gallons per annum for precipitation 1,022*l.*, filtration 270*l.* as before, manipulation of sludge almost the same as for the lime process, 200*l.* instead of 190*l.* If we refine this down to the cost per million gallons we get a cost of 81*s.* 9*d.* if the sewage is filtered. If it is not filtered, and they do not at Salford, the cost becomes 67*s.* per million gallons. Then I come to the so-called—

BARRY PROCESS.

though it is really rather a work of supererogation to discuss this process, because according to a report I saw in the newspapers the company was liquidated a week ago. Nevertheless, I will make the comparison. The Barry Company as it appears to me, has made a very bad attempt at establishing what in my opinion might have been a fairly good process. The figures are these:—Ferric liquor, 7,150 tons at 1*l.* 15*s.*, 12,510*l.*; spent lime, which I understand is spent lime from the gas works or similar material (whether they sometimes use the waste from the alkali works I do not know), of that there is 7,700 tons at 3*s.* per ton, 1,185*l.* Labour I have taken from the Salford figures the same as before, 1,700*l.*; depreciation and repairs 150*l.*, the same as before; and sand filters the same as before, also 1,275*l.* Then there is a figure added here for royalty and necessary building 50,000*l.* at 5 per cent., 25,000*l.*, making the total cost for this process 19,320*l.* Without running through the other figures the above amount for 10,000,000 gallons per annum brings this rather inferior process up to a charge of 116*s.* 10*d.* per million gallons. The next system that I have the figures for is—

THE ELECTROLYTIC SYSTEM.

And here again we have very good figures supplied from the Salford experiments. The figures are these:—

Iron electrodes, 5,400 tons, renewed every five years, 4,500*l.*; labour, 1,800*l.*—this, you will notice, is 100*l.* more than the other, and I should think it is somewhat understated even then. For depreciation and repairs we must add considerably more for this process as the machinery necessary to produce the chemical effect desired in working the process is very costly, making a sum of 1,250*l.*; coal for working engines, 1,900*l.*; sand-filters as before, 1,275*l.* Without paying any royalty (what the royalty is I do not know, or whether there is any royalty) the total cost per annum for dealing with 10,000,000 gallons of sewage is 11,725*l.* The cost per million gallons per annum for precipitation is 902*l.*; for filtration, 270*l.*; and for manipulation of sludge, which, of course, varies according to the quantity of sludge the process produces, 115*l.* Total, 1,287*l.* This works out to a cost per million gallons of 70*s.* 6*d.* The next process I come to is—

THE INTERNATIONAL PROCESS.

In this case we have to begin with seven grains per gallon of ferrozene, which amounts to 1,630 tons at 50*s.*, 4,075*l.*; labour the same as in the electrolytic process, 1,800*l.* The filters are different, they are the so-called polarite filters, six acres, and other works, which are put down to cost 52,000*l.* at 5 per cent., 2,600*l.*, which makes a total for the three items of 8,625*l.* In all the other processes the amount of precipitant which is added I have calculated into chemical equivalents, that is to say, I find, for instance, that in the "Clarine" process, to which I shall allude later, the amount of iron used, 15 grains per gallon of sewage, is chemically almost equivalent to the amount of

alumina in the alum cake used in the alumino-ferrie process, and, curiously enough, so is the iron which is dissolved in the "electrolytic" process. They are in that respect on all fours—they all add chemicals equal to this 15 grains solution of iron per million gallons. Of the ferrozone seven grains is used per gallon. If you added 11 grains to make it 18, that would make the actual amounts of iron equivalent in all cases. You would have to add one and a half times more of this ferrozone to produce the same result, so that you see it is an absolutely vital question how much of this precipitant you are going to use, because if you use seven grains you get a cost of 8,625*l.*, but if you add an amount equivalent to what is used in the other processes you get an additional 6,103*l.*, or a total of 15,028*l.* Therefore with regard to this process I have taken out the cost per million gallons as before, and I arrive at the figure of 5*ls.* 1*d.*, but if I add a larger quantity of ferrozone the cost would be 90*s.* per million gallons. This includes the cost of the filter. If you added that amount of ferrozone there would be rather more sludge. I am quite sure that if you use only seven grains you will get a very imperfect precipitation, and you are relying almost entirely on your filter for the purification of your sewage. The last of the figures I have taken out relate to—

THE "CLARINE" PROCESS.

(Of course the figures I shall give here are, I believe, quite reliable. They have been arrived at after the same fashion as the others, and the price I have taken is the price per ton at which I am informed the makers are prepared to supply the iron solution. Of this so-called Clarine 15 grains are used per gallon of sewage, or one ton per million gallons, which gives 3,650 tons at 30*s.*, 5,475*l.* The labour I have taken at 200*l.* per annum less than the alumino-ferrie and the lime, because this substance is a liquid and simply requires running into the sewage. It does not require any mechanical mixing. Depreciation and repairs I have set down at 150*l.*, as before. The cost of filters is the same, 1,275*l.* To this I have added 365 tons of lime at 10*s.*, because in some of my experiments I found I had to add lime for neutralising. Therefore I have added 183*l.* for lime. Dividing the total out in the same way, without going into details, the cost per million gallons by this process, if filtered by the same filters as before, is 5*ls.* 2*d.*, but if filtration is not employed, which I am informed is not considered in most cases to be necessary, the cost will be 40*s.* There is a certain area of sand filters, such as are commonly used by sewage engineers.

A summary of the method by which these figures are arrived at will be found in the tables appended:—

	<i>s.</i>
Barry Company (no filtration).....	116
International with the equivalent amount of ferrozone (filtration).....	90
Alumino-ferrie (filtration).....	81
Alumino-ferrie (no filtration).....	75
Electric (filtration).....	70
International (filtration).....	54
Clarine (filtration).....	
Clarine (no filtration).....	40
Lime (filtration).....	

All except the first and last processes propose to filter. The only figures I shall trouble you with now are some relating to the cost of disposing of the sludge, which is a very important matter, as we all know. Taking again the figures given by Mr. Newton in the Salford report we have these data. Raw or crude sewage contains matter in suspension amounting to probably 25 grains per gallon, which in 10,000,000 gallons per day equals:—in dry state, 16 tons; in pressed cake, 32 tons; as wet sludge, 160 tons. The following is an estimate of the weights per annum which is, I think fairly accurate, that is on 10,000,000 per day of Salford sewage. I will only cite the dry weights (the others are given in the table appended): Raw sewage gives 5,840 tons; the International process, 7,500 tons; the Electric, 6,900 tons; the Barry Company's process, 12,000 tons; the Alumino-ferrie process, 12,000 tons; the lime treatment, 11,420 tons; and the Clarine, 6,751 tons.

These are my own figures from the data given in the Salford report, and I have arrived at them after taking the amount of sludge from the raw sewage and adding the amount of ferrie hydrate, alumina, or lime salts formed by the quantity of precipitant added. In the case of lime I have assumed that it would mostly be converted into carbonate of lime. Some of it may be converted into sulphate, which of course would increase the weight, but a little of it would dissolve. So that if I take the lime as entirely converted into carbonate I think I get a fair estimate of the quantities of sludge from the lime process. The cost of manipulating the sludge is for treating it as is done at Salford, namely, running it on to draining beds and afterwards removing it, simply allowing it to accumulate. If it were collected and pressed the cost would be very considerably more, probably double, and this would naturally tell in favour of those processes which produce the least sludge.

SLUDGE PRODUCED BY VARIOUS PROCESSES.

	Dry Sludge.	Pressed Cake.	Wet Sludge.
	Tons.	Tons.	Tons.
Raw sewage.....	5,840	11,680	58,400
International.....	7,500	15,000	75,000
Electric.....	6,900	13,800	69,000
Barry Co.....	12,000	24,000	120,000
Alumino-ferrie.....	12,000	24,000	120,000
Lime.....	11,420	22,840	114,200
Clarine.....	6,751	13,502	67,509

I am sorry to have had to give so many figures, but my apology is the very obvious one that you cannot possibly treat questions of cost without so doing.

TABLE I.

ANNUAL COST AT SALFORD. (REPORT, JANUARY 1891), AND OTHER AUTHORITIES.

LIME TREATMENT (ABOUT 8,000,000 GALLONS).

	£	s.	d.		£	s.	d.
Lime treatment.....	51	10	0	per week	2,851	0	0

					<hr/>		
					10,594	0	0

LIME TREATMENT FOR 10,000,000 GALLONS PER DAY.

	£	s.	d.
Lime treatment at above rate (material and labour?).....	3,567	0	0
Sand filters, six acres and works—25,500 <i>l.</i> at 5 per cent.....	1,275	0	0
	4,842	0	0
The above cost agrees well with the figures for the Bradford lime process in 1878 (see note *), viz.....	4,670	0	0

* Cost of lime treatment at Bradford, Yorkshire, calculated on 10,000,000 gallons, in the year 1878:—

	£	s.	d.
Lime, 7½ tons per day (27½ tons at 10 <i>s.</i>).....	1,370	0	0
Salaries and wages.....	2,198	0	0
Repairs.....	203	0	0
Miscellaneous expenses.....	799	0	0
	4,670	0	0

	£	s.	d.
Cost of manipulation of sludge produced from 10,000,000 gallons, equal to 11,120 tons, dry, see Table 9, sludge from various processes.....	1,992	0	0
Cost per million gallons per annum for precipitation.....	217	0	0
Cost per million gallons per annum for filtration.....	270	0	0
Cost per million gallons per annum for manipulation of sludge.....	190	0	0
	<u>677</u>	<u>0</u>	<u>0</u>

Cost per million gallons 37s. 1d.

In Table II. will be found a full statement of the expenses at Bradford in the year 1883 on 8,450,000 gallons of sewage, which, on allowing for slightly less cost of materials, also agrees fairly well with the Salford estimate (1891 Report), the comparison being perhaps a little in favour of Bradford.

TABLE II.

ANNUAL COST OF WORKING THE LIME PROCESS AT BRADFORD IN THE YEAR 1883.

	£	s.	d.
Management.....	308	17	0
Labour.....	1,151	13	10
Rates.....	37	7	2
Lime.....	995	7	10
Coal.....	120	19	2
Coke-breeze and coke.....	56	16	9
Oil, grease, and tallow.....	50	8	0
Gas.....	33	5	7
Water.....	50	17	0
Cotton waste.....	6	12	10
Repairs to boilers and machinery.....	60	12	10
Repairs to tools and implements.....	48	19	2
Blacksmith and ironmonger.....	25	0	6
Charge for railway siding.....	11	5	7
Miscellaneous.....	31	19	1
	<u>3,302</u>	<u>2</u>	<u>1</u>

If the daily flow be taken at 8,450,000 gallons, the cost of treatment would be 2s. 2d. per 100,000 gallons.

The cost of the principal materials used are as follows:—

	£	s.	d.
Lime.....	0	10	per ton
Coke-breeze.....	0	11	"
Coal.....	6	1	"

The reduced cost of working in comparison to that of Leeds is due to the fact that the sewage flows to the works by gravitation, whereas at Leeds pumping machinery is required. Coal and lime are also cheaper than at Leeds. The materials are conveyed to the works by the railway, with which they are in communication by means of a siding.

Some of the above advantages are also in favour of Bradford as compared with Salford.

DISCUSSION.

Mr. JAMES RICHARDS gave the results of some experiments he had recently made. He stated that he had experimented with the salts of many metallic oxides, including ferrous and ferric oxides, and he had obtained about 80 per cent. of purification from albuminoid ammonia in all cases where the sulphates were used. The bichloride of mercury removed a large quantity of free ammonia as well.

Dr. CARL OTTO WEBER said that as to the "International" process he could not quite agree with Mr. Grimshaw's calculation of cost. He gave it at 90s. as compared with 54s. for the Clarine, assuming the same quantity to be used for each, but the International process employed the polarite filter, which to a certain extent assisted the action of the precipitant. A great deal of the albuminoid matter was actually removed, not by the precipitant in the International process, but by the polarite filter. He could not in any way bear out the remarks of Mr. Richards with regard to ferrous and ferric salts respectively, as he found that ferric salts were in every respect superior. This was shown in Mr. Richards' own admission that the oxygen absorbed was greater in the effluents from the treatment by ferrous salts. Other metallic oxides besides oxide of mercury absorbed free ammonia. This was notably the case with ferric hydrate.

COUNCILLOR CORBETT (Salford): I will only give you a few facts in relation to Salford such as I think may be of use. Mr. Grimshaw has quoted figures to show that the cost of the lime process is 37s. per million gallons, but that is burdening the process with filtration. Taking the lime process as carried on now at the Salford sewage works, and

allowing for the night and day treatment, the cost, as near as I can make out, is 25s. per million gallons. Last summer we had been carrying on the lime process in a rough and ready way, not trying to perfect the apparatus until we decided on our future course. In very hot weather our pumping engine broke down and at this time our other engine was being altered. The works were stopped, and we left the sewage in the tanks, on the top of the mud, which had not been cleared out for a number of weeks, and, according to all precedent, the mixture should have fermented, and given off offensive gases. But it did nothing of the kind. It lay for weeks in our tanks and we have the clearest evidence that at no time was there any perceptible nuisance. Samples of the effluent sent to several chemists without telling them what it was, showed on analysis that the effluent was an excellent one. That being so, what is a committee to do? Again, in the last few months we were working with the lime process. We got a request from the Ship Canal Company to cease operations for a time. We did so, and again under the same circumstances, except that it was a cold instead of a hot summer. Again there was no nuisance. The effluent, though at first it was alkaline, very soon became neutral so far as our rough tests would tell. Possibly the manufacturers that are being carried on in Salford may be discharging iron, or some other chemical that is required to complete the lime process. Well, if the manufactures of the borough are providing for us what is sufficient to purify our sewage we shall be well content. I take a special interest in what Mr. Grimshaw has said because I first proposed these experiments. Large experiments are now again being tried. We are going to try oxidising the lime effluent, but, beyond that, it has occurred to us that the sulphurous compounds, the chemicals in smoke, are possibly the very things wanted to neutralise the lime effluent, and we are going to try the comparative effects of aerating the effluent with the smoke of our boiler chimneys, and aerating with pure air.

The CHAIRMAN: If lime alone will purify the sewage, I do not see what need there is for further experiments, because, according to Mr. Corbett's statement, the lime process costs only 25s., and the "Clarine" process cannot beat that figure.

Mr. ARTHUR BOWLS, A.M.I.C.E.: It appears to me that the comparison of various systems cannot be made in such an off-hand fashion as Mr. Grimshaw has attempted. Of course, he explains that he has had to make various hypotheses. He has put on costs for manipulation of sludge and other matters, but it must be remembered that there are various points which have never yet been ascertained. For instance, who can tell you what the "Electrical" system has cost? The amount of coal used for the boilers to drive the dynamos has never yet been measured or weighed. The electricity has been measured, as it was at Salford, and their engineers would tell you, I have no doubt, that you can convert electricity into its horse-power equivalent by some calculation, and that you can get so many horse-power for so much coal. So you do with a certain efficiency of boiler, but then what kind of boilers have we? The only actual way of arriving at the actual cost is to weigh the coal in. That is a considerable item to be considered in arriving at correct figures on this question. I weighed every iron plate in the first experiment myself. We got at the amount of iron to a few grains, but the coal was not arrived at. I give that just as a sample of the points which have not been accurately determined, and not in disparagement of the "Electrical" system. Then there are much bigger assumptions Mr. Grimshaw had to make to bring the different processes to the same basis. By one method he makes out that the International system costs 54s. per gallon, but he says that, if you put the same amount of iron in as is used in other systems it will cost 90s. per gallon. But why should you put more iron in if it already gives a better effluent than most of the other systems on the board. That brings us to the vital question, have the systems been compared for efficiency? If the figures of Mr. Grimshaw are to be regarded as reliable, there ought to be the same purity of effluent from each. The Barry Company is put at the top as costing 116s. per gallon, but

to get efficiency you might have to spend 500s. per gallon. As a matter of fact I do not think that with that process you could get efficiency at any price. So far as possible, the conditions ought to be the same throughout, as to manipulation of sludge, filters, and other matters. Filtration was used in providing effluents from the International process, for instance, and also from the Electrical Company's process—that is to say, the results that were described in the Salford report were obtained, in some cases, after filtration. Mr. Barrow gave us the figures, and he also said that the effluents from this "Clarine" process had been filtered, but were filtered through filter-paper. It is hardly fair to compare filtration through filter-paper with filtration through sand or polarite. I would like to know whether the Clarine system has been patented, and whether there is anything to prevent a corporation or local board from using it. Is there any royalty to pay?

Mr. BARROW, in reply, said the result of his experiments conflicted with the opinion of Mr. Richards and agreed with that of Dr. Weber. The purification effected by the particular iron salt which was the main subject of his paper, had been invariably greater than the 80 per cent. obtained by Mr. Richards. It seemed to him altogether wrong to add a reducing agent like a ferrous salt to sewage when oxidation was the object aimed at.

Mr. GRIMSHAW, in his reply, said he wished to say just one word with regard to the polarite filters and the ferrozone. He would like to be as fair as he could to all the processes, and he would say that if they used the smallest quantity of the precipitate they must use a very efficient filter, which they must rely on to do the work, because seven grains of ferrozone would not do much to clarify the sewage. He would say that the "International" working with an equivalent quantity of precipitant to the other processes, and using an ordinary sand-filter instead of the polarite, would probably give as good results as with the present way of working. There was no doubt the "International" filter was a good one, and there was no doubt that so far as results went their precipitant was a bad one. Mr. Corbett should not lay too much stress on an isolated lime effluent. Untreated sewage, if allowed to stand some months, would purify itself very considerably, but of course in practice this could never be the case. In most cases lime alone did not give an effluent fit to be run away without filtering. In relation to the interesting remarks by Mr. Arthur Bowes, none of the figures were assumptions of his (Mr. Grimshaw's) own, but were in most cases estimates formed by the engineer on whom the Salford Corporation relied in their sewage report, and really those items of cost which were at all open to be called assumptions (*i.e.*, estimates), were common to the whole of the systems of sewage treatment alluded to. With regard to efficiency, he said it appeared that the systems which cost the least gave the best result, with the exception of the lime process, which, whilst it was cheapest, gave about the worst result as to quantity of sludge and quality of effluent. Of the processes he had dealt with, he put the "Clarine" first for efficiency, the "International" second, and the "Electrolytic" third. The remaining processes might be grouped together.

The discussion was then adjourned.

ADJOURNED DISCUSSION.

The CHAIRMAN reminded the meeting that the treatment of sewage had formed the subject of several papers which had been brought before the Section during the past twelve months, and, with the exception of the lime process, iron was used in some form in all the systems referred to, even in the electrical process, and the question was:—What salts of iron would be the best, and at the same time the most economical?

Dr. DREYFUS thought that in any process for the purification of sewage the two main points to be considered were: first, the cost, and secondly, efficiency. According to Mr. Grimshaw's figures Barrow's process was more costly than the lime process. He would have been glad if

Mr. Grimshaw had been prepared to show how much free ammonia was left in the sewage after the lime treatment, and how much permanganate it would take to oxidise it. This would have shown the efficiency of the Clarine process as compared with the lime process.

Mr. GEORGE E. DAVIS said that when a regular and continuous supply of a proto-salt of iron could be mixed with the sewage of any town without detection, that should be a fair test of the value of such a process, yet he had had samples of sewage from a certain town where large quantities had been added without the knowledge of the authorities, and still the effluent had not been satisfactory. With regard to the cost of the lime process, Mr. Grimshaw in his summary gave $1\frac{1}{2}$ tons to every million gallons of sewage per day. He had pointed out over and over again that this was less than one-half of the quantity necessary to destroy the albuminous matters in the sewage of any town, and was often merely sufficient to form carbonate of lime, but in exceeding the $1\frac{1}{2}$ tons great care was necessary to prevent the effluent becoming very offensive. He had found per-salts of iron more effective than proto-salts. He thought the crux of the whole question was the disposal of the sludge, and he should like to know what Mr. Barrow intended to do with it in his particular case.

Dr. GERLAND said that some 40 or 50 years ago a per-salt of iron was used to purify the London sewage, but discontinued on account of a black deposit in the River Thames. He did not think, however, that any settling backs or filtration were employed.

Mr. McCULLUM: Under heading No. 5 (International) Mr. Grimshaw gave ferrozone 18 grains per gallon, whereas he knew of places where only 9 grains were used, and this considerably reduced the cost.

Mr. BARROW, in reply, said that he had made some comparative tests, and in each case he had obtained better results. The per-centage of purification by the "Clarine" process was 73 as against 35 by the lime process. He might also remark that the effluent from the lime process was also capable of being further purified to a very considerable extent by treatment with "Clarine." It might interest some of those present to know that the albuminoid ammonia in the water of the ship canal dock was reduced some 90 per cent. by the iron process.

Mr. GRIMSHAW, in reply, said: I am pleased to find that the opinions expressed by the gentlemen who have spoken this evening are so nearly in accord with results arrived at in the two papers under discussion that I need say very little in reply to the speakers, and I therefore direct most of my attention to the criticism of the papers at the meeting when they were read. My object in my paper was to institute as close a comparison of modern results as to cost of sewage treatment by different processes as possible. It has been my impression for some time that a simple addition of a "cheap" per salt of iron together in some cases with a little lime was bound to be the precipitation process of the future. There is so little complication possible about such a process that the figures of cost are easily obtainable, with very little loophole for inaccuracy. With regard to the lime process the same may be said as also to the alum process, so far as estimates of cost are concerned. The three above-named processes, together with the international and possibly the electrical, appear to be the only possible processes at present before the public, or known in the chemical world. There are no figures which I am aware of published by the proprietors of the Electrical or International processes, and therefore I considered it the most advisable thing to take the figures given by the engineer who reported on the exhaustive and considerable trials of these two processes by the Salford Corporation. The report of this corporation is, I maintain, a very valuable contribution to our exact knowledge of the effectiveness and cost of sewage processes. As neither the International nor the Electrical Company demur to the Salford figures as in any way over-estimates of cost, I take those figures as fair to those processes. For my own part I am of opinion that they are more than fair, and that the cost to Salford of

either of those processes is likely to be more than the amounts arrived at in their report. I contend, therefore, that my conclusion that treatment with a cheap per-salt of iron of the right chemical composition is the least costly and very probably the most efficient, certainly as efficient as any known method of purifying sewage, is strengthened by any allowance we may make for what I may call the possible error of experiment in my method of comparison. Simple treatment with lime is, of course, less costly initially than by any metallic salt which is known, and even when the extra cost of manipulating the great quantity of sludge produced by lime is taken into account the same may perhaps hold good. But I hope I am not to be asked to slay the slain and vanquish the defeated by proving the utter inadequacy of lime alone to produce day by day a satisfactory effluent. Advocates of the simple lime process must produce some good modern authority for its retention before calling upon its opponents to disprove its supposed efficiency. Chemists to-day do not grant that it has any. In order to be just I would remark here that the "Davis" lime process would appear chemically to be a distinct advance on the ordinary crude lime treatment, but unfortunately it does not seem possible, on account of the very complex mechanics of the process, to give any fair approximation of the cost, and no trials of it have been made. With regard to Salford as a typical case I am prepared to show experimentally, on the large or small scale, that it is on some days perfectly impossible to precipitate the sewage with lime, whilst with a per-salt of iron and a little lime you get a clear effluent in a very short time. Occasionally in the Salford sewage you have so large a trace of iron compounds that the lime gives a very fair effluent (in appearance). With lime alone, therefore, you can do nothing satisfactory. With a basic ferric chloride you can do almost everything possible in sewage precipitation, and with such an iron salt and a little lime in special cases you can do all that is possible in the present state of our knowledge. Sulphate of alumina is a good clarifier of many kinds of sewage, but it requires a large quantity of lime for a proper decomposition, and small quantities of it do not appear to act so efficiently as small quantities of per-salts of iron. The reason of this may perhaps be found in its want of catalytic power, so to speak, in regard to acting as a carrier of oxygen to the oxidisable organic matters of sewage. It would not be contended by any chemist that this property of transferring oxygen, so marked in the ferric hydrate, is possessed at all by alumina hydrate. On the contrary, we all know that it is the intense tenacity with which the element aluminium retains its oxygen which hinders the economical production of the metal, alumina only parting with its oxygen under the intense action of the electric arc, or of metals like sodium. The great affinity of iron for sulphur is absent also in alumina compounds, there being no sulphide of aluminium, whereas the immediate combination of oxide of iron with sulphur compounds with subsequent rapid oxidation to sulphates is well known to the chemist. The only other processes which it appears possible to consider alongside that of a simple addition of a per-salt of iron, as in the so-called "Clarine" process, are the International and Electrical processes before alluded to.

These processes are what may be called "indirect" iron processes. The last named is practically a method of treating the sewage with ferrous chloride. My own suggestion of what takes place chemically is represented by the following equations:—

or to show the final result—

or

Ferrous hydrate being precipitated and hydrogen gas given off, the action being one of reduction, not oxidation.

It is claimed in this process as an advantage that the ferrous hydrate is in the nascent state, but so are all such compounds when precipitated *in situ* whether precipitated chemically or electrically, so that the same advantage is

common to all the processes under consideration. The precipitation part of the International process is in effect the addition of a very crude ferrous sulphate with some sulphate of alumina to the sewage. The so-called "ferrozone" is a very crude material produced by treating a low class mixed iron ore with vitriol. The very large amount of foreign matter in the insoluble state may, like excess of lime, assist the subsidence a little, but is certainly matter in the wrong place in the sewage sludge. This brings us to the point of the question of efficiency as between per-salts and proto-salts of iron, and in regard to this point I will only say that, with the exception of Mr. Richards, all the speakers appear to agree with me that for many reasons the per-salts are to be preferred.

The great objections to the proto-salts of course are their reducing action on the sewage and the muddy or milky effluent they tend to produce. I look on the presence of excess of ferric hydrate in the perchloride of iron as beneficial from its tendency to lay hold of the sulphur compounds, and as a neutralising body to traces of per-acid. It also probably gives density to the precipitate. Of the processes treated of, the "Electrical" and the "Clarine" processes appear to give the least amounts of sludge, but the question of sludge and its disposal is worthy of a special paper. Having said so much in general reply to the whole discussion I will briefly notice a few of the questions asked this evening. Dr. Dreyfus asked for information as to comparison of cost and efficiency of the processes. I think the two papers show clearly that the ferric process is certainly as effective, to say the least, and is apparently less costly than any process except the lime treatment. With regard to the oxygen absorbed, for my own part I certainly place more value on the albuminoid ammonia test as an indication of the impurity of sewage, and in fact consider the amount of oxygen absorbed in many cases misleading. Sewage and potable waters are not on all fours in this relation, objections in the former case not applying in the latter. Mr. Davis agrees that the proto-salts of iron are not nearly so well adapted for the precipitation of sewage as the per-salts, and I am certainly inclined to agree with Mr. Davis that such a quantity as $7\frac{1}{2}$ tons of lime to a million gallons is altogether inadequate for the proper purification of ordinary sewage, and that 10 to 20 tons is more like the right quantity. Of course the difficulty is that if sufficient lime is added for proper precipitation a most objectionably alkaline effluent results, the effect of which state of things has been that the lime treatment as generally carried out is only an apology for a process, or an attempt to satisfy the authorities. It is quite clear that in the old experiments in London with iron-salts, alluded to by Dr. Gerland, the sewage and precipitant were run away together without any attempt at previous subsidence. It did not appear to be realised at that time that the black sediment was caused by the beneficial combination of the iron with sulphur compounds in the sewage. Mr. McCullum's inquiry with respect to the quantity of "ferrozone" in the table is explained in the table itself. The just amount is that of a chemical equivalent of "ferrozone" calculated on its analysis to make it equal, chemically, to the weight of precipitant per 10 million gallons in the other systems.

The cost according to the smaller amount of ferrozone said to be necessary is also given. The International system has a very poor precipitant, but apparently a good filter. Whether a filter as good or better could not be made at a less cost is open to a good deal of discussion, and what is the actual cost of the polarite filter would first require to be accurately ascertained. In conclusion I hope that my reply will have cleared up any points in the paper which were in any way obscure.

ON AN AUTOMATIC APPLIANCE FOR RECORDING THE PRESENCE AND DENSITY OF BLACK SMOKE IN FACTORY CHIMNEYS.

BY WILLIAM THOMSON.

SOME years ago it suggested itself to me that if some simple method could be devised of actually recording the density of smoke passing up the chimney, and the length of time during which that smoke was passing, by an automatic apparatus, it would give some tangible means of aiding in the prevention of black smoke from factory chimneys. It is evident that if such a record could be obtained the diagram of the smoke produced during the working day might be pasted on to a board and compared with the results of other days, when the question of carelessness in firing would be definitely shown. This would thus form a check upon the firemen in working the furnaces, and the best record might be taken as a standard of what is possible in each furnace or series of furnaces. With a view of making this possible I have made a number of experiments in different directions, and at last succeeded in getting what I thought would be an accurate record of the density of the smoke, together with a record of the lengths of time during which it was passing, by exposing in the chimney strips of ordinary writing paper exposed in front of a slit against which the flue gases impinged. On placing a piece of paper into a smoky chimney and withdrawing it after a few seconds I obtained a dark mark on the paper, which approximately corresponded with the amount of smoke passing up; but on fixing this in an apparatus provided with a slit behind which the paper was drawn I found that a mark was given to begin with, but little or no mark produced afterwards when the paper became very hot. It was evident therefore that the high temperature prevented the deposit of the soot on the paper.

By taking two strips of paper, heating the one over a Bunsen burner and leaving the other cold, and passing both through a smoky flame, I observed that the cold paper became more deeply marked with black deposit than the strip which had been previously heated. In obtaining these diagrams, therefore, it would be necessary to have arrangements for keeping the paper comparatively cold.

The apparatus which I have devised is by no means perfect, but I submit it to the Society as it is, with the hope that others who have more time and opportunity of working these things may take up and continue this investigation, with a view of arriving at a comparatively perfect appliance by which to get a record of the time during which smoke is passing up the chimney, and of the density of such smoke. The appliance which I have devised consists of two brass tubes about 5 ft. long, the one $1\frac{1}{2}$ in. and the other $\frac{5}{8}$ in. internal diameter, placed the one within the other, leaving an annular space of about a quarter of an inch between them. A cut is made lengthwise through both tubes to a distance of about 3 in. from the end, the circles of both tubes being thus bisected, at the end of which another cut is made at right angles to the first one. A semi-circular plate is then soldered, so as to join both tubes at the end of the 3-in. cut, and another semi-circular plate is fixed in the opposite direction at the bottom, the two spaces left between the two tubes and the two semi-circular pieces having flat plates soldered so as to join the two longitudinal tubes and to make them watertight. A plate of metal is arranged to slide on to the cut portion of the two tubes in which a slit is made at right angles to the length, and a strip of paper is held against this slit by a roller and spring, the end of the strip of paper being connected with a chain which is pulled up at a regular velocity by means of clockwork. The apparatus which I have devised pulls about 4 in. of paper past the slit during each hour.

To work the apparatus the paper is adjusted, and a pencil mark drawn along the slit from the outside, so as to mark the position of the paper at the beginning of the experiment. The apparatus is provided with a narrow piece of copper tube which passes down the annular space to the bottom, and another small piece of wider tube is fixed into the outer tube about 6 in. from the top. Cold water is delivered

at the bottom of the apparatus by the narrow copper tube, the hot water produced by the hot flue gases being allowed to flow away by the small tube inserted in the top of the outside tube of the appliance. By allowing a constant flow of water through the apparatus it is kept comparatively cool. The clockwork is set going as soon as the end of the tube is inserted into the flue, preferably by a hole through the top of the flue, and the apparatus allowed to work during the time it is desired for obtaining the diagram.

A number of diagrams obtained by the apparatus were exhibited.

SESSION 1891-92.

March 7th.—Mr. Sidney Lupton, "Criticisms and Suggestions towards the Improvement of British Measures."

Meeting held Monday, December 7th, 1891.

MR. JAMES SHARP IN THE CHAIR.

FAST AND FUGITIVE DYES.

BY PROF. J. J. HUMMEL.

(This Journal, 1891, 832.)

DISCUSSION.

THE CHAIRMAN said that it was most important that the colours imparted to textile, and especially to woollen fabrics, should be fairly fast, but there was still a large demand for what were called "steamed colours," which were well known to be loose, although the difference in cost was very trifling, not amounting to more than 1s. or 2s. per piece. In 1858 he was present at the reading of Dr. Perkins' paper in which the discovery of the aniline colours was announced, and soon obtained samples and dyed goods with them. These colours were branded as fugitive, but the value produced at the present time was not less than 7,000,000*l.*, and taking the cost of applying them at thrice, and the value of the fabrics at 10 times this amount, they had, for this "vagabond" trade, a commercial turnover of nearly a hundred millions sterling, a business which was not to be despised. Some of the natural dyes were not less fugitive, and if a colour were discovered which took the eye of the public the inventor was sure of his reward, whether the colour was permanent or not. It should be remembered that a large proportion of the loose work which had been referred to was exported to

the East, where little expense in tailoring was incurred, and the goods were only worn for a short period and cast aside.

He was of opinion that without new processes of manufacture, and probably new materials also, it was utterly impossible to make these colours fast enough to resist either exposure or chemical reagents. The lighter bodies as a rule produced the most fugitive colours, and their life was less in proportion to the number of sulphonic groups introduced. Many points were involved in the question of exposure. The condition of the dyes and mordants employed had considerable influence, and the results would vary materially with the weather and the seasons. He could not understand the deep brown shade taken by the pattern of picric acid yellow, and thought some other than the ordinary atmospheric conditions must have been present, since in the course of his large experience as a manufacturer he had never seen such a reaction. He was also surprised that Professor Hummel should class Prussian blue as a fast and Nicholson's blue as a fugitive colour. These dyes were both colourless in the bath, and developed by acids, and in his experience neither would stand the action of alkalis.

Mr. LUTON hoped that in a later paper Professor Hummel would deal with the important question of resistance to scouring, as well as to exposure to light and air.

Professor SMITHILLS thought that the chemical reactions involved in the fading of the various dyes were of the greatest importance, although scarcely anything was known about the subject, and he hoped that, notwithstanding its extreme difficulty, Professor Hummel would take it up in the near future, and in due course communicate the results to the Society. With regard to the supposed action of ozone and hydrogen peroxide, recent researches had shown that their presence in the atmosphere was very doubtful, and that the reactions which had been attributed to them were in reality due to nitrous acid.

Mr. THORP WHITAKER, secretary of the Society of Dyers and Colourists, inquired whether the quantity of mordant employed with those colours which required mordanting was the same in all cases, or varied with each colour. He was surprised at the marked fading of gallocyanin, which was generally regarded as a fairly permanent colour. There was no doubt that in many cases the coal-tar colours were faster than the vegetable ones they had replaced.

Mr. UNDERHILL inquired whether barwood should be used in conjunction with indigo. He said that vat-dyed indigo shed very much on the body and underclothing, and inquired whether there was any means of fixing it more securely on the fabric.

Mr. SYDNEY LUTON inquired whether the copper mordant of which Professor Hummel had spoken was a solution of cuprous or cupric oxide in ammonia, or whether both oxides were present, and what proportion of copper was fixed on the fibre.

Dr. LEWKOWITSCH would have been glad if Professor Hummel had said more about the influence of the chemical constitution of a colouring matter on its permanency.

Mr. WILKINSON was surprised that Professor Hummel should have classed catechu as a colour which did not require a mordant, since copper, or some other oxidising agent was always used with it, and though very fugitive without such treatment, he considered that, with it, it was was one of the fastest of colours, and compared very favourably with indigo. He mentioned that Prussian blue, though generally a fast colour, was fugitive in limestone districts.

Dr. COHEN was not aware that aniline black was applied to silk and wool, and inquired in what way it was dyed on these fibres.

The CHAIRMAN said that although it could be fixed on wools, it was not very satisfactory, but that it was largely used on silk. The process was regarded as a trade secret.

Professor HUMMEL in reply said, that in his opinion both fast and fugitive colours had their legitimate uses. He did not quite concur with the Chairman's view that sulphonation necessarily diminished the fastness of colours to light, but that this was rather influenced by the general constitution of the colour, and the position of the sulphonic group. Comparing the fastness of the acid azo-reds with those fixed direct on the fibre, in which in general no sulphonation had taken place, it would be noted that this point had little influence on their permanency. His experiments must at present be regarded as merely preliminary, and designed to test the permanency of the colours actually in use in a practical way, and he hoped later to be able to answer many of the further points which had been raised. He intended to examine the chemical effects produced on some pure colouring matters when exposed to light in India, but he feared that this would by no means give a complete answer to Professor Smithell's question, since in many cases the fibre had an important influence on the permanency of dyes, as in the instance of tartrazine, which was fast on wool but fugitive on silk.

In reply to Mr. Whitaker's question as to the amount of the various mordants employed, Professor Hummel said that they were varied in accordance with the results of a long series of experiments made in the Yorkshire College to determine the most advantageous quantity in each case. Though gallocyanin was undoubtedly a useful colouring matter, it was not to be compared in permanency with members of the true alizarin group, and it was to be regretted that it was frequently sold under the misleading name of "Alizarine purple." In reply to Mr. Underhill's question as to the propriety of using barwood as a preliminary to vat-indigo, although there was no doubt that in itself it was a fugitive colour, it appeared to enable the indigo to penetrate the fibre better, and to render it less liable to rub off. As the dyers said, "the indigo follows the wood." In addition it counteracted the greenish tinge of the indigo, and produced a richer and more "bloomy" colour. The effect seemed to be largely due to the mere boiling of the wool, which softened the hard and horny keratin, and enabled the indigo to penetrate more freely. If the purplish shade were really necessary, it might be obtained more rationally by the use of faster colours, such as alizarin. Objection might be taken to the use of bichrome mordants, with Alizarine red, but other chromium and aluminium mordants might be substituted. Alizarine red was already being used for the purpose with beneficial results, and if the fastest possible colour were required, it was difficult to suggest any other means. Alizarine blue was at least as fast as vat-indigo, but the Government had discovered that when it was employed the wool fibre was considerably weakened, owing presumably to the oxidising action of the bichromate, which certainly had a tendering effect if carelessly used. In one case, however, which had come under his knowledge it was discovered that the rotting action which had been attributed to bichromate used in conjunction with Alizarine blue, was due to quite another cause. His colleague, Mr. Liechti, was at present engaged on minute investigation of the action of chromium mordants on the wool fibre, and hoped before long to bring the results before the Society.

In reply to Mr. Sydney Lutton's question as to the exact character of the ammoniacal copper solution employed by Scheurer in his experiments, Professor Hummel said that it consisted of cupric hydrate dissolved in ammonia, and would therefore have some solvent action on the cellulose of the fabric, and possibly coated the colours with a parchment like protection.

Referring to Dr. Lewkowitsch's inquiry as to the relation of molecular constitution to fastness, he stated that his investigations were not as yet sufficiently advanced to allow of generalisation, but that in the case of the eosins, the introduction of an ethyl or methyl group into a particular part of the molecule increased its fastness to light.

With regard to Mr. Wilkinson's remarks as to catechu, Professor Hummel regarded the action of the bichromate as mainly oxidising rather than mordanting, although some chromium-oxide was undoubtedly fixed on the fibre along with the brown japonic acid. He had himself been rather surprised at the want of fastness of the sample, and thought

it possible that this was due to the fact that no copper sulphate, but only potassium bichromate had been used in this particular experiment. He agreed with Mr. Wilkinson's remarks with regard to Prussian blue.

He confirmed the Chairman's reply to Dr. Cohen with regard to aniline black, and said that though it was not generally known, it was perfectly true that aniline black could be fixed on wool, while it was already largely applied to silk. Although he could not enter into the details of the process, he might say that the principle consisted in the use of somewhat unstable metallic chlorates, which exerted the requisite oxidising power under the influence of steam heat.

Referring generally to the subject of fugitive dyes, he hoped on a future occasion to be able to give more definite and detailed replies to some of the questions than he had been able to do that evening.

MR. C. A. FAWSITT IN THE CHAIR.

NOTES ON THE PRODUCTION OF CYANIDES.

BY D. J. PLAYFAIR.

IN 1878 Messrs. Tcherniac and Gunzburg took out a patent for a process for making ferrocyanides from sulphocyanides. This consisted in heating to redness a mixture of six equivalents of sulphocyanide of potassium, five of lime, five of carbon, and one of iron. The iron used was in a spongy form, obtained by reducing the iron of pyrites to a metallic state by a reducing atmosphere in a specially constructed furnace. As the result of the reaction, they claim that the sulphur of the sulphocyanide combines with the calcium and iron leaving the potassium all as cyanide, which is converted into ferrocyanide on lixiviating. Without being aware of this patent, I tried a similar experiment,

modelling it on the reaction of a black-ash furnace, but obtained only a very small yield of prussiate. At best the product would only be ferrocyanide, which would require purifying and a subsequent furnacing operation before cyanide could be arrived at, so I did not follow up this experiment.

In studying the decomposition of sulphocyanides one experiment consisted in heating a mixture of the sulphocyanides of sodium and potassium in an atmosphere of hydrogen. The sulphocyanides were placed in a glass combustion tube, and heated to redness, while a constant stream of dry hydrogen gas was passed through the tube. At the outlet from the tube sulphuretted hydrogen began to be evolved as soon as the heat attained to redness, and continued coming off freely for more than half an hour, although the amount of sulphocyanides experimented upon did not exceed a very few grammes. The experiment was interrupted and the contents of the tube examined.

About 80 per cent. of the sulphocyanides was found to be decomposed, resulting in the formation of sulphide and cyanide of potassium and sodium. Sulphide and cyanide were found to be present in nearly equal quantities, or about 20 per cent. less cyanide than would be required for the equation—

Apparently not more than half the sulphocyanide can be expected to be obtained as cyanide by this method, and it is in a very impure state, being mixed with a large quantity of sulphide, the separation of which would be troublesome and costly.

The above experiment was varied by using an atmosphere of hydrocarbons instead of hydrogen. Vapour of naphtha was employed, and as before, when the heat was raised sulphuretted hydrogen was freely evolved. At the end of the experiment the contents of the tube were examined, but no cyanide was found. The decomposed sulphocyanides were converted into sulphides, with traces of formates.

Sulphocyanide of sodium heated along with charcoal in a crucible at a bright redness was found to yield a small quantity, not much more than a trace of cyanine and a large quantity of sulphide.

More satisfactory results were obtained when a metal was employed to deprive the sulphocyanide of its sulphur. The only two metals, which I have found suitable, are lead and zinc.

Without detailing the preliminary experiments in crucibles, with charges varying in size from a few grammes up to 8 or 10 lb., and in which the metals were used in a granulated state, sometimes so fine as to be able to pass through a fine sieve, it will be sufficient to describe the method now employed, which is as follows:—

An oblong vessel with rounded bottom, in fact the shape of an inverted muffle, made of plumbago, with a well-fitting lid is used. The muffle is placed in a sort of cradle, which is attached to a rope passed over a pulley fixed to a beam above a small furnace. In the top of the furnace is a hole just large enough to admit the muffle. The muffle is lowered down into the furnace, and rests on bearers so that its bottom and sides are exposed to the heat, but its top is an inch or two above the top of the furnace. The metal, say zinc, is first put into the muffle, along with a slight sprinkling of charcoal to maintain a reducing atmosphere, and the cover is put on till the zinc is melted. As soon as the zinc is melted an equivalent quantity of sulphocyanide of soda is added. The sulphocyanide is put in either cold in a dry state, or from an adjoining pot, in which it is maintained in a state of fusion.

As the heating proceeds, the sulphocyanide becomes very fluid lying above the melted zinc. The charge is well agitated to stir up the zinc into the sulphocyanide. As soon as the required temperature is reached, the charge suddenly becomes very thick, and begins to glow, especially in the track of the stirrer.

When this occurs, it is the sign that the reaction is complete. The cover is put on the muffle and the whole is hoisted out of the furnace and allowed to cool. A good deal of heat seems to be evolved in the reaction, because if there be an excess of zinc, it is given off in vapour and

bursts into flame at the edge of the cover a few minutes after the muffle is removed from the furnace. If the sulphocyanide be in excess, no zinc flame appears.

When cool the charge comes away from the muffle easily, and there is no appearance of the material of the muffle having been acted upon. The fused mass should be of a uniform pearl-grey colour throughout, in which case it will yield a solution free from soluble sulphides. If the charge be over-fired, part of it will have a dull brown or even a reddish appearance. Such will yield a solution containing sulphides of the alkali. When using the muffle above described, the charge is so much under control, and the reaction can be so closely watched, that generally no alkaline sulphide or only a trace of it is found in the charge. In the earlier experiments in large crucibles this was a difficulty that presented itself, as the portion of the charge next the bottom frequently got over-fired, producing sulphide of soda, sometimes to the extent of 15 parts per 100 of cyanide. The reaction that goes on in the muffle is expressed thus:—

The loss in weight of the whole charge in the furnacing operation is about 5 per cent., half of which is accounted for by the moisture in the sulphocyanide used. Some cyanate and a trace of carbonate are formed in the process.

When a slight excess of zinc is used, no sulphocyanide remains undecomposed, but there is a slight loss of zinc as vapour, and some double cyanide of zinc and sodium is formed, in a badly burned charge to the extent of 15 parts of cyanide of zinc per 100 of cyanide of sodium. Using, however, a slight excess of sulphocyanide instead, the amount of cyanide of zinc formed is reduced to about two or three parts per 100 of cyanide of sodium. The finished product in that case contains a little undecomposed sulphocyanide, but the loss of zinc is avoided, and the result is a better article.

The lixiviation of the fused mass, which is the next operation, presents no difficulty. It is lixiviated in the ordinary way in a set of vats, like black-ash vats, except that in this case the lixiviation is intermittent, as the solution does not filter downwards through the insoluble matter. The crude cyanide is stirred up at each lixiviation, and, on the insoluble matter settling, the clear solution is decanted or pumped from one vat to the next one. In this way a solution from the strong vat is obtained of about 35° Tw., containing 24 grms. of cyanide of sodium per 100 cc., while the last washing of the weak vat is 0° Tw., and contains under 4 per cent. NaCy.

This last weak liquor is quite clear, but, on attempting to wash out the last traces of cyanide of sodium from the sulphide of zinc, one gets a milky solution that does not settle clear, till it is mixed with a stronger solution of cyanide of sodium. It is quite possible to have a 30 per cent. solution from the strong vat, but this does not settle so well as one of 24 or 25 per cent.

If the liquor contain any cyanide of sodium, it is agitated with cyanide of lead, which is easily formed by precipitating a portion of the solution with chloride of lead, settling and decanting off the solution of chloride of sodium.

The insoluble matter, consisting of sulphide of zinc, amounts to about 65 per cent. of the fused mass.

An analysis of the solution ready for evaporating is as follows:—

Expressed in grammes per 100 cc.

Cyanide of sodium	22.0
Cyanate of sodium	3.66
Double cyanide of zinc and sodium	1.55
Carbonate of soda	0.71
Sulphocyanide of sodium	1.8

The strong solution of cyanide of sodium is now put into a vacuum pan, and evaporated to the consistency of a thick paste, which solidifies on cooling.

The finished cyanide contains about 26 per cent. of water, and about 55 per cent. of cyanide of sodium, not including that existing as double cyanide.

This contains the same amount of available cyanogen, or hydrocyanic acid, as a cyanide of potassium of 73 per cent.

By subsequent heating the whole of the water can be driven off without much loss of cyanide.

An analysis of the product of the vacuum pan is as follows:—

Cyanide of sodium	54.7
Cyanate of soda, including formate	9.45
Double cyanide of zinc and sodium	3.9
Sulphocyanide of sodium	1.3
Carbonate of soda	1.65
Water	27.0
	<hr/> 100.0

In the above described process the yield of available cyanide averages about 70 per cent. of the possible yield according to theory. In the evaporation in vacuo, the loss of cyanide, due to the decomposition of its solution when heated, is from 2 to 4 per cent. of the cyanide present, provided that the vacuum be good, say, equal to 26 in. of mercury, and provided also that the strength of the solution be about 33° Tw. If the solution be half that strength to start with, or the vacuum poor, the loss is more than doubled.

Instead of zinc as above described, lead may be used to decompose the sulphocyanide. It has the disadvantage, that, owing to its high equivalent, more than 3 lb. of lead are necessary to do the work of 1 lb. of zinc, also that in the fusion it does not stir up into the sulphocyanide so easily as zinc. On the other hand, it has the advantage, that it does not form a double salt with the alkaline cyanide, even although cyanide of lead is soluble to some extent in cyanide of sodium.

Whichever metal is used, the resulting sulphide may be treated by ordinary processes to reduce it to the metallic state again, or, in the case of zinc, zinc salts may be made direct from the sulphide.

Other metals were tried in place of lead and zinc, but not with satisfactory results.

Tin, for instance, reduced the sulphocyanide to cyanide, but the sulphide of tin, which was formed, dissolved to a large extent in the alkaline cyanide.

Copper is also unsuitable, as the product is a cuprocyanide.

Other sulphocyanides, such as the sulphocyanides of potassium and barium, behave like sulphocyanide of sodium, and give similar yields, about 70 per cent. Sulphocyanide of sodium has the advantage of being cheaper than the others, and, on account of the low combining weight of sodium, gives a cyanide of a higher strength.

The sulphocyanides may be manufactured directly, or may be obtained as by-products in gas-making. Dr. Lunge states the amount of sulphocyanide of ammonia in English gas-liquors at about 25 lb. per 160 gallons.

In no gas-liquor, of which I have been able to get samples, has the quantity reached anything like that figure. In Scotch gas-liquor, after it has been treated for the extraction of ammonia, I have found only about 1 lb. of sulphocyanide of lime per 100 gallons. The refuse lime from gas purifiers contains sulphocyanides in larger proportion, but even this gas-lime from Scotch gasworks I find to contain under 20 lb. of sulphocyanide of lime per ton. In gas-lime there is a large amount of hyposulphite of lime, which would require to be entirely removed from the sulphocyanide, as the presence of oxygen compounds is prejudicial to the formation of cyanides from sulphocyanides. The small quantities in gas residues above mentioned are not worth the cost of recovering, so it is preferable to make the sulphocyanides by direct processes.

DISCUSSION.

The CHAIRMAN considered the paper was one of much interest and importance, as the cheapening of cyanides would have a beneficial effect on several industries, notably the extraction of gold by cyanides; and seeing the sulphocyanide, from which the cyanide was prepared, would be an outlet for bisulphide of carbon, it would come as a boon to manufacturers of this article, as in some districts the consumption had been gradually decreasing, owing to the

india-rubber manufacturers having stopped using it in the manufacture of waterproof cloth. He agreed with the author as to the extraction of sulphocyanides from gas residues entailing considerable expense, as the amount of material which would have to be dealt with would be very large for a small return of sulphocyanide, and the finished article would not be easily purified; whereas in the case of bisulphide of carbon a pure sulphocyanide could be prepared with comparatively little trouble. As regards the fixation of nitrogen by alkalis carbon, although a large amount of money and trouble had been expended in testing it at different times, its success had never been accomplished, and he thought the chief reasons were: First, the high temperature required; 2nd, the serious wear and tear of the apparatus; 3rd, the large percentage of cyanate produced, which could not be reduced economically to cyanide. Some trials he had made a few years ago produced very little cyanide, and that at a prohibitive cost. He was somewhat surprised to hear that the cyanide survived the fusion in contact with melted zinc so well, but no doubt it was conducted out of contact with the atmosphere. The fusion of the sulphocyanide of potassium with metallic iron seemed to be the weak point in the process which was patented by Gölis, which he had tested and found to work smoothly until this point was reached, when he only obtained 25 per cent. of the theoretical yield of cyanide. In the evaporation of cyanide solutions at ordinary pressures it was well known that a serious loss occurred, and it was a new idea to him to use a vacuum pan, but it commended itself as a good way out of the difficulty. Instead of converting sulphocyanides into cyanides by fusion, it seemed to him far more rational to try and get an economical method whereby it could be done in solution. It was well known that in acid solutions sulphocyanides could be converted into cyanides by using permanganate of potash, and he had tried peroxide of hydrogen which acted equally well, but the cost was prohibitive in both cases, and the fact of it taking place in an acid solution was inconvenient, as the hydrocyanic acid would require to be condensed, besides the unpleasantness of working an apparatus containing such a poisonous gas. He had tried one or two experiments in an alkaline solution, but they gave practically a negative result as far as cyanide was concerned, the nitrogen coming off principally as ammonia. No doubt cheaper oxidising agents, such as manganate of soda and manganese dioxide in acid solutions would give good results, and there would be produced sulphate of manganese which is a saleable by-product, but the condensation of the HCN would have to be faced. He further said that the item of cost was the most important factor in Mr. Playfair's process, and he would ask him if he had formed any idea as to the cost at which he could produce cyanide compared with the method now in use.

In concluding the Chairman congratulated Mr. Playfair at having grappled with a difficult subject, and hoped he might be rewarded by the complete success of his process.

Dr. J. B. READMAN desired to know if Mr. Playfair had made any attempts at carrying out Bunsen and Playfair's results by trying to manufacture cyanide in the blast furnace. In these experiments it appeared that the potash was derived from the coal, while it was not certain whether the nitrogen was derived from the air or from the fuel. They were all familiar with Mond's work on the preparation of barium cyanide, but why should not potassium cyanide be manufactured in the blast furnace under suitable conditions? There appeared to him great hope of success in that direction.

Mr. E. RODGER said that the question he had intended to ask had been anticipated by Mr. Readman. He believed that certain experiments carried on recently in the Durham district in the manufacture of cyanide in the blast furnace pointed to hopeful results. He would suggest the use of a water-jacketed furnace for such work, as in this way the silicious lining, which would of course be attacked by the alkaline mixture necessary for the production of cyanide, could be dispensed with and the furnace could be used very economically.

Mr. W. FOULIS thought that the recovery of sulphocyanides from the waste lime of gas-purifiers could not be carried on profitably. He had found that the cyanides produced in the manufacture of coal-gas were decomposed when the gas was passed through the lime purifiers and appeared as ammonia. He had recently instituted a number of experiments, and had been successful in removing the cyanides from the coal-gas before it reached the purifiers. The cyanide was obtained in considerable quantity, and his results had been so encouraging that further experiments were being prosecuted. He had no doubt that a large quantity of cyanide would before long be obtained from coal as a by-product in the manufacture of coal-gas.

Mr. PLAYFAIR, in reply, said that he had not tried to repeat or follow up Bunsen and Playfair's experiments in the way of manufacturing cyanide in the blast furnace, because he considered that later experiments on the fixation of nitrogen at high temperatures by the action of alkalis carbon—none of which had been conspicuously successful—were, generally speaking, founded on Bunsen and Playfair's results. Besides this, the experimental use of a blast furnace for the manufacture of cyanides would have involved him in much expense. The quantity of sulphocyanide in all the lime residues from gasworks which he had examined was so low as not to make them worth working. He presumed that Mr. Foulis recovered his cyanides as sulphocyanides, or in some other form, which would require further treatment. He could not give any exact figures as to the cost of his process, but estimated it to be at least 25–30 per cent. less than the cost of the other processes in use at present.

THE ENGLISH PROCESS OF ANTIMONY SMELTING.

BY EDWARD RODGER.

The smelting of antimony is one of those processes about which little trustworthy information is to be obtained from those text-books which profess to afford instruction upon metallurgical operations. I do not know what the case may be with regard to the generality of metallurgical processes, but I can say that, so far as those with which I am practically acquainted are concerned, the text-books almost always may be taken as teaching anything rather than the processes by which metals really are obtained from their ores.

There are some honourable exceptions, of course, but the vast proportion of so-called metallurgical works simply copy the errors and repeat the obsolete processes which previous authors have committed to writing; as a rule there is far too little original inquiry, and too much convenient faith amongst compilers of these works.

I need not here point out the errors which are committed in almost every work regarding the process of antimony smelting. I may only say that during a not inconsiderable study of the published processes, I have never seen a complete account of the real method, and therefore I hope that the few notes which I have the honour to bring before you to-night will not be without interest and value.

I presume that it is needless for me to give any account of the ores of antimony, nor of its history. These things are so well known that any reference to them would be superfluous. Suffice it to say that the one which I have seen smelted is a sulphide mixed with quartz, the "stibnite" of the mineralogists, and which contains about 52 per cent. of metallic antimony.

The ores for smelting by the English process must be free from lead and arsenic, neither of which metals can be eliminated, and an ore of such a poor quality as that which I have mentioned is costly and unsatisfactory to deal with.

The ore arrives in this country generally in smallish pieces, rather larger than ordinary road metal, and is packed in bags holding various weights: about a hundredweight

may be taken as a rough average. The ore is ground under edge runners, and passed through a coarse screen, the largest pieces which are allowed to pass being about the size of hazel nuts, while the great bulk of the ore consists, of course, of smaller particles, varying from the size of peas to fine dust.

After grinding, a sample is prepared which is analysed or assayed in order to ascertain how much iron is required for proper reduction.

The process of smelting consists in reducing the sulphide of antimony by means of metallic iron, the fusion taking place in crucibles which are heated in a very long reverberatory furnace.

In dealing with the process, we may first of all consider the furnace and the crucible, then passing on to the details of the actual operation of smelting.

The furnace is a curious structure, and differs from any other species with which I am acquainted. It consists of a bed 54 feet long, including the fire-places, and 7 feet 4 inches broad (inside size), covered by a low arch which springs almost from the surface of the ground, the bed itself being sunk below the level of the ground. This long gallery is heated by means of a fire-place at each end, the two fires drawing into a common flue in the middle of the furnace. The flue is arranged below the bed of the furnace, and the ports are in the bed, this arrangement being to prevent the heat being drawn to one side, as would be liable to happen were the flue to start directly from the side of the furnace. The sides of the furnace and the top of the arch are covered with 1-inch cast-iron plates, while a 2-inch square malleable iron bar runs on each side the whole length of the furnace under the upright binders, which are, of course, tied over the top of the arch by tie-rods.

The floor of the furnace-room along the whole length of each side of the furnace is covered with cast-iron plates, coming out about 3 feet from the walls of the furnace, the remainder of the floor of the furnace-room being paved with granite "setts."

It will be seen from this description that the furnace is very little above the ground level. It is, in fact, sunk into the ground, so that it is quite easy to step on to its iron-covered roof. The fire-places being below the ground level, suitable fire-pits are, of course, required.

The crucibles are lowered into their places from above through holes in the arch, with corresponding apertures in the iron binding plates, the workmen standing on the roof of the furnace while handling the crucibles. Indeed, practically all the work is done by the furnacemen while in this position. The holes referred to are circular, 14 inches in diameter, and are 42 in number, 21 on a side, in such a furnace as is here described. In addition to the "pot-holes," there are two holes in the furnace roof at each end of the bed, which are 4 inches in diameter, and are used for cleaning away clinker, &c. from the ends of the bed. The "pot-holes" are each provided with a circular fire-clay cover clamped round with an iron ring, which serves to protect the covers, and also to bind them when they split, as they generally do.

The crucibles stand 20 inches high and 11 inches outside across the mouth. They are constructed of a mixture of good fire-clay and plumbago. The clay may be either Stourbridge or Hexham, the former for choice; and the plumbago, whatever its source, must be free from iron, &c. Below are analyses of the two classes of clay referred to:—

	Stourbridge.	Hexham.
Water (H ₂ O).....	7.00	7.44
Silica (SiO ₂).....	69.00	59.05
Alumina (Al ₂ O ₃).....	22.00	25.61
Protoxide of iron (FeO).....	1.50	2.20
Lime (CaO).....	0.39	0.88
Magnesia (MgO).....	0.51	0.75
Potash (K ₂ O).....	0.41	1.97
Soda (Na ₂ O).....	0.18	0.28
Titanic acid (TiO ₂).....	..	1.53
	101.12	99.71

The crucibles weigh 12 lb. dry, and consist, as nearly as need be, of—dry clay, 35 $\frac{1}{2}$ lb., and plumbago, 6 $\frac{1}{2}$ lb. The amount of clay and plumbago made up at one time is 5 cwt. of clay and 3 qr. 11 lb. plumbago. This mixture is ground under edge runners in a damp state, and then thoroughly incorporated by treading with the bare feet in the usual manner of preparing clay for crucible-making, this part of the process calling for no remark. The crucibles are made in the usual way by hand, and are considered to cost, using the above proportions, about 2s. 6d. each, or thereabouts. They are dried and stoved in the ordinary way, steam pipes being used for the first drying, while the waste heat from the antimony furnace is employed for the final drying. After thorough drying they are carefully heated to redness, in suitable kilns, before being placed in the furnace. These kilns are simply upright chambers, provided with a high door in front, and communicating with a chimney at the top. Below is a fire-place, over which is built a low arch whose top is levelled by means of fire-clay covers, and is pierced with a number of pigeon-holes, so as to provide for the passage of the flame from the fire-place below into the upper chamber. The crucibles are placed upon the floor, leaving the holes clear. When the chamber is full the door is closed and luted; a gentle fire is made, which is cautiously augmented until the crucibles are at a cherry-red heat, at which temperature they are kept until required, when they are withdrawn as needed.

I have said that the furnace contains 42 holes in two rows, 21 holes in each row. The pair of crucibles nearest the fire-places at each end of the furnace is kept for "starring" or refining the crude metal, while the remaining holes are divided as is found suitable for the first and second meltings of the crude metal. The charge for each crucible consists of 42 lb. of ground ore, 16 lb. of wrought-iron scrap, 4 lb. of common salt, and 1 lb. of skimmings from the next operation or else the same weight of impure slag from a previous melting. Of course these weights vary with every ore, but the above will be true for an ore of 52 per cent.

The iron scrap used must be wrought not cast iron; tinned scrap is preferred, the small trace of tin being generally believed, I know not with what truth, to whiten the resulting antimony. Part of the tinned scrap is beaten up into a round ball, large enough to fit the top of the crucible loosely. Such a ball weighs about 13 lb., and one is used for each charge, the remaining iron required being added in the form of turnings or borings, and is mixed through the ore, along with the salt, in the weighing scoop.

The mixture of ore, salt, and iron is dropped into the crucible through an iron funnel, the lump of beaten scrap being thrown in last of all, so as to form a kind of lid; the furnace hole is then closed with its cover for about half an hour, when the crucible is again examined. In the meantime a fresh charge is weighed out ready for the crucible the moment it is empty. As the charge melts the ball of iron on the top falls down and is gradually absorbed, the iron reducing the antimony to the metallic state, it being itself converted into sulphide. The salt assists the separation of the slag, and tends to promote the fusion of the siliceous matters of the ore.

The workman from time to time examines the crucible with a view to ascertain whether fusion is taking place properly, and presses down the ball of scrap on the top with a bar of iron. The length of time required for fusion and decomposition varies with the position occupied by the crucible, those far from the fire requiring longer time than those close to it, but as a rule about four meltings are got from each crucible per 12 hours, so that allowing for charging, and occasional changing of crucibles, &c., a little less than three hours may be taken as an average, but it must be borne in mind, that the richer the ore, the shorter time is required to melt it. Opposite to each crucible, except those used for the final refining, is placed a conical cast-iron mould, which stands close by the furnace side, it is large enough to hold the contents of the crucible, and is furnished with a cast-iron lid. The fusion being complete, the crucible is withdrawn, balanced on the edge

of the furnace wall, and the contents poured into the mould, which is at once covered with its lid; the crucible is examined, scraped out if need be, replaced, and at once recharged with the mixture.

The mould is pierced at the bottom with a circular hole about three-quarters of an inch or less in diameter; the metal does not escape through this, as the first portion which reaches the mould chills and prevents the escape of the remainder; the object of this hole being to enable the fused mass, when cool, to be knocked out by means of a hammer and a punch. When the mass is removed from the mould the reduced antimony which collects at the bottom is knocked away from the slag, which slag, if the fusion is carefully conducted, should be quite clean enough to be thrown away. The metal obtained by this process is known as "singles," and below is an analysis of a sample of such metal:—

Antimony	91.63
Iron	7.23
Sulphur	0.82
Insoluble matter
	<u>99.68</u>

It is seen by the analysis that the "singles" contain a large quantity of iron, this arises from the necessity of using an excess of iron in order to reduce the whole of the antimony in the ore, and the next operation consists in removing this large excess of iron, and thereby practically purifying the metal. This is accomplished by melting the "singles" with a small quantity of pure sulphide of antimony, the liquated sulphide being used for this purpose. I have here a sample of liquated sulphide such as is used in this process, and also in the preparation of the "antimony flux," to which I shall refer later.

The charge for the second fusion consists of 84 lb. of singles broken small (about the size of road metal) and 7-8 lb. of liquated sulphide of antimony, with 4 lb. of salt added as a flux. Sometimes kelp salt is used in place of ordinary salt in this fusion, and is found to be very suitable. The reaction in this fusion is similar to that in the last operation, the excess of iron in the metal reducing the pure sulphide of antimony to the metallic state, being itself converted into sulphide of iron. The fusion is narrowly watched, and great care taken that the metal and the sulphide of antimony shall mix thoroughly, but much stirring with iron tools should be avoided at this stage as the object is to remove iron so far as possible. When stirring is required it is done as quickly as possible in order to expose the iron stirrer as little as may be to the action of the sulphide of antimony. When the fusion is complete, the fused mass is carefully skimmed by means of a cast-iron ladle placed on a long shaft, this skimming being carried out as completely as may be in order that the metal should be as clean as possible before pouring. When the skimming is over the metal is at once poured into moulds identical with those used in the previous operation. The resulting metal from this melting is known as "star bowls," and each fusion yields a lump of about 80 lbs. The skimmings go, as I indicated before, to the first operation.

I have here samples of this second metal, which yielded on analysis:—

Antimony	99.53
Iron	0.18
Sulphur	0.16
	<u>99.87</u>

As you will see, the surface of the crystals of this metal are covered with tiny bright specks. These specks are a certain sign of the presence of sulphur in the metal, and this appearance is known as "flouring," metal showing these specks being said to be "floured." As in the first melting it is necessary to add an excess of iron in order to remove all the antimony, so in this case it is necessary to add an excess of sulphide of antimony in order to remove all the iron, and hence the presence of sulphur in the antimony

obtained. In order to remove this sulphur, and finally to purify the metal, another melting is required, and the custom of the trade being that antimony shall be sold in flat ingots, each "starred" or crystallised on the upper surface, it is necessary to take precautions so as to obtain this "star" or crystallised appearance, by means of which the buyer judges of the purity of the metal. These two results are achieved by melting the metal along with a peculiar flux known as "antimony flux," and this antimony flux is a body not easily prepared, and one which is often difficult to obtain at first, but having obtained it, it is easily kept in order.

The process of making this flux is a rule-of-thumb one, and is carried out something in this way:—Three parts of ordinary American potash are melted in a crucible, and two parts of ground liquated sulphide of antimony are mixed in. When the mixture is complete and the fusion quiet the mass is poured out and tried on a small scale in order to see whether it yields a good "star" or not; if it does so the ingot of metal obtained is broken, and the metal examined in order to judge whether or not it is free from sulphur. Should this prove the case the flux is considered satisfactory, and may be put in use, but otherwise the flux is remelted and more of one ingredient or the other is added as experience dictates, the forming of a good flux being a matter of some difficulty, and one in which experience is the only guide.

The process of refining and starring the star-bowls is as follows:—The lumps of metal when cold are removed from the mould and carried from the furnace house to an adjoining room, where they are thoroughly cleaned from the adhering skin of slag by chipping with sharp hammers, this part of the work being sometimes done by women, who become very expert in rapidly and completely removing every trace of slag. Unless this cleaning process is carefully carried out it is hopeless to attempt to obtain a good star on the finished metal, the presence of the adhering slag completely ruining the appearance of the ingots, rendering them dull and lustreless and quite unlike what they should be. The chippings are of course collected and returned to the second melting. The star-bowls having been cleaned they are broken small as in the case of the singles, and a charge weighed out for refining. The charge used is 84 lb. of star-bowls, and a sufficiency of the antimony flux. Enough flux is added to surround the ingots completely, and for this less or more is needed according to the shape and thickness of the ingots, for ingots of the ordinary shape about 8 lb. are required. The melting takes place in the crucibles next the fire-places, that is to say, in those which are hottest and in which the fusion will be most rapid.

The charge of metal is thrown into the crucible and narrowly watched, and whenever it begins to melt, the flux is added. As soon as the fusion appears to be complete the furnaceman stirs the mixture once round only with an iron rod, and the charge is at once poured out. The ingot moulds are placed side by side, having between them a wedge-shaped frame of cast iron, called a "saddle," the edge of which points upwards, and upon which the charge is poured, when the stream divides, one half finding its way into each mould. These moulds are left to cool quite undisturbed, and as they cool the flux which covers the surface cracks, and when quite cold can be easily knocked off. The flux is used over and over again, a piece of carbonate of potash being thrown in each fusion when old flux is used. In this way it will be seen that the flux keeps on increasing as a little potash is added and a little sulphur and antimony are picked up at each fusion. The ingots must be completely surrounded by flux, there must be a thin layer of it between the mould and the metal, and also the whole surface of the ingot must be covered to the depth of perhaps a quarter of an inch. Under the circumstances the metal should always give a good star and preserve a good colour.

The traces of flux which adhere are removed by washing in warm water with the assistance of a little sharp sand, water by itself being insufficient to remove the flux, which is practically insoluble in water.

The personnel of such a furnace as I have described consists of about 36 men and three women, this total being made up as follows:—

2 Firemen, one each fire, day and night.....	4
8 Furnacemen, 4 on each side, day and night ..	16
2 Men, cleaning metal, day and night	4
2 Men, breaking metal, day and night	4
1 Man, weighing charges, day and night	2
	30
On day-shift only—	
3 Men, labouring, grinding ore, &c.....	3
1 Smith, repairing tools, &c.....	1
1 Packing and washing, 3 women, and.....	1
1 Engine and boilerman.....	1
	36

Of course this does not include the making of crucibles, &c., but generally speaking one crucible-maker and one labourer can make enough crucibles, working during the day only, to keep the furnace going. The coals used, including those used for firing the kilns, amount to about 22 tons per week, or a little more than one ton and a half each shift.

About 11 crucibles are used per ton of refined metal produced, but this might be reduced by careful working, and the yield of finished metal from such a furnace as I have described working a 52 per cent. ore is about 14½ tons, or a little more, perhaps 14 tons 12 cwt. per week.

A great deal of volatilisation takes place from the melted metal in the pots, and the fume thus produced is condensed in the flues of the furnace, which are built for that purpose in a winding manner, passing backwards and forwards under the floor of the crucible drying stoves, so as to dry the pots at the same time as condensing the fume. The total amount of fume varies very much; the richer the ore the less fume there is in proportion to the antimony produced, although the absolute amount of fume is greater than when a poorer ore is worked. I suppose, taking one case with another, that I am not far from the truth when I say that about 10 per cent. of the total antimony contained in the ore is volatilised, and of this the greater part is condensed in properly constructed flues, but, of course, some part is inevitably lost. The fume is a whitish body, heavy, and rather crystalline, not very unlike white arsenic in appearance, but of a greyer colour, and, as you will readily believe, generally more or less blackened with soot. It contains about 70 per cent. of metallic antimony, one sample, of which I have an analysis, taken from about 7 tons of fume, gave 72·60 per cent. metallic antimony. The smelting of this fume is conducted as follows:—A test experiment is made in order to ascertain the amount of carbon in the form of coke or anthracite necessary to reduce all the antimony present in the fume. This having been found, the fume is mixed by grinding under edge-runners with the proper quantity of carbonaceous matter, and of the mixture so produced a few pounds weight is added to each charge of ore and iron when melting for singles. This process of smelting fume is no favourite with the workmen, as the gases given off in the process are apt to cause the mixture in the pots to overflow, and the “boiling ore,” as they term the mixture of fume and coke, is therefore looked upon by them with great disfavour; but beyond the mechanical difficulties, there is no trouble whatever in smelting the fume. The flues require cleaning out at intervals, sometimes once every two or three months, sometimes less frequently, according to circumstances.

The ingots, which are known in the trade as “French metal,” after being wrapped in straw, are packed in kegs holding about 6 cwt. nett, and which are about the size of ordinary butter firkins.

The value of any sample of antimony is judged, not by analysis, but by its appearance, and a good sample of metal should exhibit the following characteristics:—The star should be bold and defined, standing well up on the metal, the edges of the ridges sharp and straight; the metal itself should be lustrous and white, not dull and leaden-looking. Lastly, on breaking the ingot, the crystals should be large, and the surfaces of them free from specks, which are a sign of sulphur in the metal, a most undesirable

impurity; and on this last point, perhaps more than on any other, depends the value placed on the sample under consideration.

I regret that I cannot offer any idea of the costs of working, as, unfortunately, I have lost or mislaid the notes bearing on that part of the process. I have thought it best, therefore, to confine myself solely to a description of the process as it is carried out in practice, leaving out of sight the commercial considerations altogether. I must not forget to acknowledge the kindness of Dr. Readman, who placed his notes and analyses at my disposal, in order to fill up some blanks in my own memoranda.

DISCUSSION.

The CHAIRMAN said that the thanks of the Section were due to Mr. Rodger for his instructive and practical paper, and all the more so as he had come forward with it on very short notice to supply the place of another which had been postponed. He quite agreed with Mr. Rodger that the information which could be got from ordinary text-books on this subject was of little practical value, as he had lately to look up this subject, and could not get the desired information. He would like to ask if any special quality were required or if any great difficulty was experienced in grinding metallic antimony, as he had occasionally to use it and found it difficult to obtain and the price very high. He would also like to know what the average life of a crucible was, and if the process he had described was worked in Scotland.

Dr. J. B. READMAN could say from experience that Mr. Rodger had given a very accurate description of the smelting of antimony. The process was, he thought, defective so far as the use of crucibles were concerned. These should be dispensed with, for the use of crucibles for smelting was a very costly method, each crucible costing 2s. 6d., and all of them filling only a small proportion of the heated area of the furnace. Why should not a reverberatory furnace or some other form of furnace be employed, and the enormous expense of crucibles be got rid of? Some time ago a method had been proposed for smelting antimony in a water-jacketed blast furnace, but he did not know if it had been successful. He thought a blast furnace of that description might be adapted to serve the purpose. On the whole he thought there was great room for improvement in the process of refining antimony.

Mr. RODGER, in reply to Mr. Fawsitt, said that any antimony could be ground in an iron mortar, but it was very difficult, almost impossible, to get it chemically pure. However, a good sample of antimony as it left the smelter's hands was a very pure commercial product. The cost of the crucibles was immense. In the work with which he had been connected they calculated that eleven crucibles were used for every ton of refined metal produced. The average life of a crucible depended on what it was used for. Crucibles used for “sturring” were very short lived, and could not be employed more than three or four times, being rapidly destroyed by the flux, while crucibles for “singles” would stand for a long time and could be used twenty times or more. A blast furnace, he believed, had been used for smelting antimony, but the furnace was worked very low, with poor ores, the object being to produce as much “fume” as possible, this fume being condensed and afterwards reduced with carbon. He had, however, no practical experience of this. He agreed with Dr. Readman that a vast amount of heat and space was lost by the use of crucibles for smelting. A reverberatory furnace had been tried but did not seem to work. Antimony was not now smelted in Scotland, the work with which he had formerly been connected having been stopped for want of ore. Newcastle was at present the seat of the industry.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Manufacture of Glass Pipes of Large Diameter. L. Appert. Bull. Soc. d'Encouragement l'Industrie Nationale, 1891, 6, 114—121.

See under VIII., page 38.

PATENTS.

Improvements in Machinery and Apparatus for Grinding or Crushing Mineral, Vegetable, and Animal Substances. W. H. Thompson, London. Eng. Pat. 19,061, November 24, 1890. 11d.

This invention relates to improvements in the class of grinding mill in which a ball is held between two discs surrounded by a cylindrical casing, so that rotary motion applied to the discs causes the ball to travel along the inner circumference of the casing, thereby exerting a reducing and grinding action upon any materials enclosed therein. The principal point of novelty claimed consists in securing the two discs each to an independent shaft placed axially in line with the other, each shaft being capable of separate adjustment laterally as well as axially, and of being driven at independent speeds. In another arrangement the two discs are secured to the same shaft, and fitted with springs for self-adjustment. Or a rotary casing may be employed, the discs being held stationary and in elastic contact with the ball, an arrangement specially applicable when the

casing is placed horizontally and the discs fitted to a vertical spindle. The accompanying drawing shows one of the

GRINDING APPARATUS.

latter arrangements, suitable for wet grinding, with the driving pulley placed underneath.

There are seven claims and four sheets of drawings. —B.

Improvements in Filtering Machinery. E. Martin, Watford. Eng. Pat. 19,600, December 2, 1890. 6d.

The apparatus consists of a horizontal cylinder, with perforated circumference, carried on hollow trunnions, which is immersed nearly to its full depth in a cistern filled with the liquid to be filtered. The trunnions pass through the sides of the cistern by means of stuffing-boxes, and over the whole circumference of the cylinder, except for the small portion projecting above the liquid, is laid an endless filtering cloth, which runs thence over secondary small cylinders or rollers and passes through another cistern, in which are provided means for cleaning off any deposit that may have collected. The liquid passes through the cloth surrounding the cylinder, leaving its impurities on the outer surface of the cloth, whilst the clean liquid is withdrawn through the trunnions. On motion being imparted to the cylinder and the filtering cloth, the deposit is removed as the latter passes through the second cistern.

Claim is made for the whole arrangement. —B.

Improved Method of and Apparatus for Treating Smoke and Gases from Furnaces and other Fires. A. S. Davy, Sheffield. Eng. Pat. 179, January 5, 1891. 8d.

See under II., next page.

Improvements in or Connected with Compression Pumps for Gaseous or Vaporous Fluids. W. H. Webb, Bootle. Eng. Pat. 1540, January 28, 1891. 8d.

The patentee makes the suction or lift-valve of a pump removable by securing its seat in a round plug, which can be inserted through a suitable opening in the pump casing.

Four claims and two illustrations. —B.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

II.—FUEL, GAS, AND LIGHT.

PATENTS.

Improvements in Appliances for Producing Light by Incandescence. T. Heskin, Preston. Eng. Pat. 16,821, October 22, 1890. 8d.

THESE improvements relate to the production of light by heating magnesia or other refractory earthy substances to incandescence by means of Bunsen or other gas burners, and to the automatic supply and renewal of such substances. Hitherto mantles or hoods, which, owing to their fragile natures, are liable to be fractured and broken, have been used. Further, the light-giving properties of such are found to deteriorate, necessitating frequent renewal.

The principal feature of this invention is the preparation of a mixture of a salt of a refractory earth with glycerin, "which, when suitably applied to the flame of the burner, evolves a continuous supply of the refractory earth."

The burner used is preferably one giving a low, short, but hot flame, about half an inch in height.

Fig. 1.

Fig. 1 shows one way of applying the mixture. T is a metallic or earthenware vessel, 4 in. high by 2 in. in diameter, extending to 6 in. or other suitable size, at the base for attachment to a Bunsen burner. The base B is fixed about $\frac{1}{4}$ of an inch above the central air-way of the burner, and is about $\frac{1}{2}$ an inch less in diameter than that of the flame, to allow a clear annular space for the air to ascend. h h h is a circle of small tubes of thin platinum, nickel, or silver, fixed at right angles to the base, each $\frac{1}{4}$ in. long and $\frac{1}{8}$ in. in bore, about $\frac{3}{16}$ th of an inch apart, and which almost touch the flame of the burner at a point $\frac{1}{16}$ th of an inch below its extreme height. T is filled with the pasty mixture, which eventually appears as a bead at each end of tubes h h h. When the burner is lighted, the mixture decomposes, the bead swelling out and immersing itself in the body of the flame—a residue of refractory earth being left generally in the form of a small cone. If the ends of the tubes actually touch the flame, the oxide is left in a light porous condition, not so well adapted for illuminating purposes as the denser form.

The reservoir T may be placed above or below the Bunsen and wires of platinum nickel or silver may be drawn through the pasty mixture and brought in contact with the flame. Fig. 2 shows suitable shapes of wire, which in case

of (a) is $\frac{1}{32}$ nd of an inch thick and $\frac{1}{16}$ th in the other two (b), (c). When heated, decomposition occurs, and tufts of oxide are left adhering. When the burner is not in use,

Fig. 2.

ATTACHMENT FOR INCANDESCENT GAS LAMPS.

the mixture in the tube being deliquescent, absorbs moisture from the air and forms another bead, which in turn evolves a further supply of oxide when decomposed. The chloride or other suitable salt of magnesium, lanthanum, zirconium, yttrium or thorium may be used.—D. A. S.

Improvements in Incandescence Gas Lamps and Apparatus in Connection therewith. C. Clamond, Paris, France. Eng. Pat. 60, January 1, 1891. 8d.

ACCORDING to these improvements the gas first passes through a regulator, consisting essentially of a disc with small holes the area of which can be regulated by means of tapering pins; it is claimed that in this way the quantity of gas can be varied without altering the speed of the gaseous current through the holes, and hence without altering the mixture of gas and air. After passing through the regulator disc, air mixes with the gas, being drawn in through lateral perforations in the conducting tube, and the mixture is heated on its way to the burner, which consists of a metal chamber having at its underside a group of small tubes extending downwards. The air and gas are here intimately mixed, and on issuing from the lower ends of the tubes meet a further supply of highly-heated air, sufficient to ensure perfect combustion. The flame so produced plays downwards through an inverted magnesia hood, which it raises to incandescence, the products of combustion then passing upwards to the regenerator for heating the preliminary mixture of air and gas and secondary air supply. By these means, it is claimed, there can be no clogging of orifices by particles of soot or carbon. For powerful lamps of this class the burner as described above is somewhat modified in order to ensure an even distribution of air and gas supply to the tubes, while in order to avoid the inconvenient radiation of heat from the glass globe, the latter is cooled by being surrounded by a second glass globe, an air space being left between the two, through which the air supply passes on its way to the regenerator and thus undergoes a preliminary heating.

For details of the regenerator and mode of fixing these lamps, the specification and drawings must be consulted.

Improved Method of and Apparatus for Treating Smoke and Gases from Furnaces and other Fires. A. S. Davy, Sheffield. Eng. Pat. 179, January 5, 1891. 8d.

IN this method the smoke and gases are caused to pass through a fan, blower, or exhauster, in the interior of which they are brought into contact with water in the form of spray, the solid matter being precipitated and subsequently carried off. The water is led in to the vane spindle and projected by centrifugal force through holes therein. The spindle is hollow or tubular, and partially divided longitudinally by ribs. There may also be holes through the boss, or through the arms of the vanes, or the water may be supplied through the easing to the interior of the fan or exhauster, and so dashed into spray by the revolving vanes.

—D. A. S.

Improvements in or relating to Means or Apparatus for Treating Gases, Smoke, and Products of Combustion so as to render them Innocuous. R. Wainwright, Leeds. Eng. Pat. 10,427, June 19, 1891. *Sd.*

IN this invention it is proposed to render gases and smoke "innocuous" by drawing them from the chimney or flue through a cooling pipe or tube into a purifier in the form of a tank partially filled with water, and thence into the atmosphere. The chimney being closed with a damper, the products of combustion are withdrawn by means of an exhaustor, cooled by being passed through a tube surrounded with water, and discharged beneath the surface of water in a closed tank. They are thus efficiently washed without the use of any mechanical agitator. From the purifier the gases are allowed to escape into the atmosphere direct, or are returned to the chimney above the damper, or to the furnaces again. A drawing is attached to the specification showing the application of this system to a Cornish boiler.—D. A. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Origin of Petroleum. R. Zoloziecki. Chem. Zeit. 1891, 15, 1203—1205.

THE author disputes the validity of the hypothesis of Okenius concerning the origin of petroleum, the chief features of which are the assumption that the formation of petroleum has been brought about by the action upon the fatty matter of decomposing animal remains of certain salts, notably alkaline bromides and aluminium chloride, and the contention that this view is borne out by the composition of the saline constituents of the natural waters commonly found associated with petroleum. The chief grounds for his rejection of this theory are that petroleum and the said saline deposits belong to different geological epochs, and that little or no nitrogen in any form is found in the waters accompanying deposits of mineral oil. Moreover, cases are known in which the water accompanying petroleum is free from saline constituents, and further, the syntheses of hydrocarbons of the aromatic series effected by the aid of small quantities of alkaline bromides and iodides and aluminium chloride, take place under conditions widely differing from those that would occur in the production of petroleum in contact with an aqueous solution of these bodies. In consequence of these considerations he adheres to his belief that the function of the saline constituents of waters accompanying petroleum has been rather to restrain the putrefactive changes of the original animal matter, than to cause a specific alteration of its fatty constituents into hydrocarbons of such series as are generally found in crude petroleum.—B. B.

Artificial Mineral Lubricating Oils—the Condensation Products of Allyl Alcohol with Methylated Benzenes. G. Kraemer and A. Spilker. Ber. 1891, 24, 2785—2793 and 3164.

IN their investigations on the condensation of cinnamene (styrol) with methylbenzene derivatives (Ber. 1890, 23, 3269—3283; this Journal, 1891, 38 and 39) the authors briefly referred to the formation of viscous cinnamene compounds possessing the properties of mineral oil. In continuation of these researches they have attempted to ascertain in what relation these compounds stand to mineral oils. Owing to the fact that the viscosity of mineral oils increases as the quantity of solid paraffin diminishes, it is feasible to attribute the formation of viscous compounds to certain changes which paraffin has undergone after the formation of petroleum. The conversion of solid paraffin into liquid products has been investigated by a number of

authors, and although it is unnecessary for the purpose of the present paper to gain further insight into the nature of this dissociation, the authors contend it to be highly probable that the liquid hydrocarbons thus formed while acting mutually on one another may in course of time be resolved into viscous compounds resembling the products which are obtained by the condensation of cinnamene with methylbenzene derivatives.

The new compounds described by the authors were prepared by mixing 100 cc. of anhydrous allyl alcohol with 1,000 cc. of pseudocumene and treating the mixture gradually whilst cold with 100 cc. of concentrated sulphuric acid and 50 cc. of fuming sulphuric acid. Two layers of liquid were formed, the heavier of which contained sulphonic acids. The lighter portions were separated, washed with water and soda, and distilled in a current of steam. At 200°—220° a colourless viscid liquid came over, the residue forming a yellowish-brown resinous compound. The oil after fractionation boiled above 300° almost without decomposition. It had a viscosity of 775 at 15° (water being 1) compared with the figure 40 which was obtained in the same apparatus with a sample of best Russian lubricating oil. It had the composition $C_{21}H_{28}$. The resinous compound was found to be a polymeric of the original substance. The liquid obtained from xylene and allyl alcohol had the formula $C_{15}H_{24}$, and showed the lower viscosity number of 8.1. It will be seen that oxygen was not present in these compounds, and from this fact it was supposed that they had not been produced under the same conditions as the cinnamene derivatives, but that the condensation must have been accompanied by the elimination of water. The formation is illustrated by the authors in the following manner:—

The product obtained from pseudocumene and allyl alcohol is therefore dimethyldicumylmethane. The authors regard these compounds as the "viscosity carriers" of mineral oils; moreover they consider they have proved that the lubricating property depends on the number of methyl groups present in the compound, and that all high boiling fractions of petroleum are free from oxygen whilst the highly viscous oils contain less hydrogen than the oils of lower viscosity.

The authors explain on page 3164 of the *Berichte* that they omitted to refer to the researches of Baeyer (Ber. 6, 224), who obtained a viscous compound of high boiling point by the condensation of allyl alcohol and mesitylene with concentrated sulphuric acid, although no mention was made by him of the constitution or composition of the product.

PATENTS.

A New Product possessing the Same, or nearly the Same Properties as Spirits of Turpentine. T. Drake, Huddersfield. Eng. Pat. 16,916, October 23, 1890. *Ad.*

See under XIII., page 45.

Production from Mineral Oils of Sulphonic Acids and Sulphones, and the Manufacture of a New Product by treating Gelatinous Matters with Sulphonic Acid. A. M. Clark, London. From the "Gewerkschaft Messel," Grube Messel, Germany. Eng. Pat. 19,502, November 29, 1890. *6d.*

THE unsaturated hydrocarbons present in petroleum, mineral wax, or rosin oil are converted into a mixture of sulphonic acids and sulphones when treated with fuming

sulphuric acid at the ordinary temperature, or with acid containing 10 per cent. of the anhydride at 80° C. Petroleum of sp. gr. 0.860–0.890, when thus treated, yields a syrupy liquid containing these sulphonic acids. When this liquid is run into water the acids are partially precipitated, their complete precipitation being effected by the addition of common salt. The precipitate is redissolved in water, and reprecipitated by the addition of brine, this operation being repeated until all the sulphuric acid is removed. The sulphones can be separated from the sulphonic acids by converting the latter into their sodium salts and then extracting the former by means of ether or of naphtha. The sodium salts, when dissolved in water and decomposed with hydrochloric acid, yield the free sulphonic acids, to which the name of "*Tumenol-sulphonic acids*" is given. These bodies when moist form a syrupy paste having a spicy taste, and drying at 110° C. to a pulverisable residue. They dissolve readily in water, but are precipitated from solution by common salt, hydrochloric acid or sulphuric acid. The alkaline salts are soluble in water, while those of the alkaline earths and of the heavy metals (except antimony and mercury) are insoluble. The free acids are readily oxidised, and are specially characterised by their property of precipitating glue and gelatin from slightly acid solutions with the formation of an elastic caoutchouc-like precipitate which may be drawn into threads.—C. A. K.

IV.—COLOURING MATTERS AND DYES.

Addition of Hydrogen to Tricyclic Systems. E. Bamberger. Ber. 1891, 24, 2463–2469.

THE tricyclic compounds, anthracene and phenanthrene, take up 2 and 4 atoms of hydrogen respectively, but since there is no clue to the position of the added hydrogen atoms, the author has investigated the products of the reduction of the naphthoquinolines (compare following abstracts). The reduction is perfectly comparable with that of bicyclic acid compounds; it takes place in two stages, in each of which 4 atoms of hydrogen become added. The first group of 4 hydrogen atoms is taken up by the pyridine nucleus, and this reduction to tetrahydride is effected by means of tin and hydrochloric acid. In the second stage of reduction, which yields an octohydride, 4 hydrogen atoms are taken up by one or other of the two rings of the naphthalene nucleus; this is effected by means of sodium and amyl alcohol. The tetrahydronaphthoquinolines behave like bicyclic compounds, and, in fact, resemble alkylated naphthylamines in their properties. Similarly, the octohydrides behave as monocyclic or benzene derivatives. The second stage of the reduction may take place in either of the two rings which constitute the naphthalene nucleus, and the classes of octohydrides obtained, are distinguished as *aromatic* and *alicyclic* hydrides.—A. K. M.

Ethyl-α-Naphthylamine. E. Bamberger and C. Goldschmidt. Ber. 1891, 24, 2469–2472.

ETHYL-α-NAPHTHYLAMINE readily reacts with diazo-compounds, yielding azo-dyes, which on reduction yield ethyl-1:4-naphthylenediamine.

Phenylazo-ethyl-α-naphthylamine has been previously described by Eicker, whose results the authors confirm. *Sulphophenyl-azo-ethyl-α-naphthylamine* forms a dark carmoisine red crystalline powder of green metallic lustre; it dissolves in hot alcohol with a bluish, deep red colour, in concentrated sulphuric acid with a violet colour, and in alkalis with an orange-red colour. Its sodium salt, $C_{18}H_{16}N_3 \cdot SO_3Na$, separates as a deep red precipitate on the addition of salt to its aqueous solution.

Ethyl-1:4-naphthylenediamine hydrochloride—
 $C_{12}H_{14}N_2 \cdot 2HCl$

obtained by the reduction of the above dye with a solution of stannous chloride in hydrochloric acid, forms silvery needles which become greenish on exposure to the air, and which do not melt at 300°. It dissolves very readily in water, and sparingly in concentrated hydrochloric acid. The free base forms a colourless oil having an odour resembling that of crude α-naphthylamine. It is sparingly soluble in cold water, much more soluble in hot water, readily in the ordinary organic solvents, and when exposed to air and light it rapidly becomes dark in colour.

When it is treated with hydrochloric acid, hydrogen sulphide, and ferric chloride it gives a slight brown colouration and turbidity; with aniline, potassium dichromate, and glacial acetic acid it gives a brownish-red colour, which becomes deep Bordeaux red on boiling; and with potassium dichromate and meta-tolylenediamine a bluish-green colour which changes to red on boiling.

The *chlorimide* obtained by the action of bleaching powder on an acid solution of ethylnaphthylenediamine, gives a deep red colouration with an alcoholic solution of aniline and hydrochloric acid.—A. K. M.

Tetrahydro-α-naphthoquinoline. E. Bamberger and L. Stettenheimer. Ber. 1891, 24, 2472–2480. (See also this Journal, 1891, 999–1000.)

THE authors prepared α-naphthoquinoline by Skraup's method, which, however, they have modified in some respects. The product melts at 52° and boils at 223°, under a pressure of 47 mm., and at 338° under a pressure of 719 mm., and not at 251°, under 747 mm. pressure, as stated by Skraup. It crystallises from light petroleum in clear colourless thick monoclinic tables, and when quite pure has a very faint odour, unlike that of quinoline. When ferric chloride is added to its solution in fuming hydrochloric acid, a compound of naphthoquinoline hydrochloride with ferric chloride separates, which is very readily soluble in water, and which crystallises from alcohol in golden yellow silky needles.

Tetrahydro-α-naphthoquinoline—

is prepared by gradually adding a solution of α-naphthoquinoline (20 grs.) in hydrochloric acid to a boiling mixture of tin (80 grs.) and 38 per cent. hydrochloric acid (500 grs.) and heating until the metal is dissolved. The purified base crystallises in snow-white, lustrous scales, melting at 46.5°; it dissolves readily in the ordinary solvents, and its solutions exhibit an intense blue fluorescence, which is destroyed by the addition of a trace of an alkali or mineral acid. Oxidising agents produce an intense carmoisin colour when added to its acid solution, and when potassium dichromate has been employed and the solution allowed to stand a few minutes, the chromate of a new base separates, and when crystallised from boiling water, is obtained in the form of lustrous dark green needles resembling quinhydrone. *Tetrahydronaphthoquinoline hydrochloride*, $C_{10}H_{12}N \cdot HCl$, crystallises in thick vitreous prisms, melts at 260°–261°, dissolves sparingly in hydrochloric acid and not very readily in water. The *nitroso-derivative*, $C_{10}H_{12}N \cdot NO$, crystallises from light petroleum in flat, broad, lemon-yellow prisms, melting at 59.5°.

Phenylazotetrahydro-α-naphthoquinoline—

crystallises from dilute alcohol in groups of cherry-red needles, exhibiting a bronze lustre; it dissolves in concentrated sulphuric acid with a cornflower-blue colour, and in organic solvents with a deep orange-red colour. Its

sulphate ($C_{13}H_{11}NH.N_2.C_6H_5)_2.H_2SO_4$, crystallises in flat olive-green prisms, and gives violet-red solutions.

Sulphophenylazotetrahydro- α -naphthoquinoline—

forms a dark violet-red crystalline powder, exhibiting a bronze lustre, and yielding red solutions; its sodium salt forms an orange-red crystalline precipitate.

Paramidotetrahydro- α -naphthoquinoline, $C_{13}H_9N_3$, obtained by the action of stannous chloride and hydrochloric acid on the sulphophenylazo derivative, is unstable, dissolves readily in alcohol and in ether, and the solution exhibits a green fluorescence. Its hydrochloride, $C_{13}H_{11}N_3.2HCl$, crystallises in white needles, which do not melt at 300°, and which dissolve readily in water, sparingly in absolute alcohol, and very sparingly in strong hydrochloric acid. Its slightly acid solution gives with bleaching powder a yellowish white chlorimide, readily soluble in alcohol and ether. With hydrogen sulphide, hydrochloric acid, and ferric chloride it gives a brownish-red colour; with alkaline α -naphthol and exposure of the product to the air, it gives a greenish-blue precipitate; with aniline, acetic acid, and potassium dichromate, a brownish-red colouration, which becomes deep bordeaux on boiling; with meta-tolylene-diamine, acetic acid, sodium acetate, and ferric chloride, a deep reddish-brown colouration.

When the hydrochloride is fused with aniline hydrochloride and some free aniline and amidoazobenzene, a deep violet-red melt is obtained, which dissolves in alcohol with a very intense reddish-violet fluorescence and a violet colour. The formation of such fluorescent dyes distinguishes the paraminines of naphthalene from those of the benzene series.—A. K. M.

"Aromatic" Octohydro- α -naphthoquinoline. E. Bamberger and L. Stettenheimer. Ber. 1891, 24, 2481—2495. (See preceding abstract.)

Ar.-octohydro- α -naphthoquinoline—

is obtained by the reduction of α -naphthoquinoline by means of sodium and amyl alcohol. It crystallises in thick plates, melts at 47—48°, boils at 216° under 37.5 mm. pressure, is somewhat volatile in steam, and has a characteristic sweet odour. Like the "aromatic" hydronaphthylamines, it reduces alcoholic silver nitrate solution; with ferric chloride in an acid solution it gives a carmoisin colouration on warming, which disappears on cooling; with potassium dichromate a similar reaction, but the colour soon appears also in the cold; with chromic acid it gives a deep violet-red colouration, which rapidly disappears. The hydrochloride, $C_{13}H_{17}N$, HCl crystallises in monoclinic plates; the hydrogen sulphate, $C_{13}H_{17}N.H_2SO_4$, in wavelite-like aggregations, is very readily soluble in water, softens at 183°, and melts at 187°; the picrate, $C_{13}H_{17}N.C_6H_3O(NO_2)_3$, melts at 155—156°; the platinochloride ($C_{13}H_{17}N)_2PtCl_6$ appears to exist in three different forms, which differ in colour and in the amount of water of crystallisation which they contain. The nitroso-derivative, $C_{13}H_{16}N.NO$, melts at 77.5°; the acetyl-derivative, $C_{13}H_{16}N.C_2H_3O$, forms colourless vitreous prisms, melting at 68—69°; the methyl-derivative, $C_{13}H_{16}N.CH_3$, crystallises in large thin nacreous plates, melting at 37—38°, and its hydriodide in long, silky needles, melting at 202°.

Ar.-octohydro- α -naphthoquinoline-azobenzene sulphonic acid, $C_{13}H_{16}N_2.C_6H_4.SO_3H$, forms slender violet-brown needles, sparingly soluble in water and alcohol and soluble in concentrated sulphuric acid to a deep violet solution. In an acid bath it dyes wool and silk a bright red.

When diazobenzene chloride reacts with octohydro- α -naphthoquinoline in the presence of an excess of sodium acetate, a reddish-yellow product separates, and when this is warmed with dilute sulphuric acid, phenylazo-octohydro-naphthoquinoline sulphate is obtained. It crystallises in magnificent cherry-red prisms with a bronze lustre, melts at 190.5°, and dissolves in concentrated sulphuric acid with an olive-green colour. The dye-base forms lustrous orange-red prisms, melting at 118.5°.

Ar.-octohydroparamido- α -naphthoquinoline—

obtained by the reduction of the above octohydro- α -naphthoquinoline-azobenzene sulphonic acid by stannous chloride and hydrochloric acid, crystallises in groups of radiating flat white prisms, melting at 97°, and is not affected by light and air. Its hydrochloride crystallises in lustrous white needles, readily soluble in water, and its solution gives the following reactions:—With hydrochloric acid, hydrogen sulphide, and ferric chloride an intense and beautiful crimson (Thionine); with meta-tolylene-diamine hydrochloride, sodium acetate and ferric chloride, it gives the Tolylene-blue and Tolylene-red reactions; with a solution of α -naphthol in dilute potash, it shows the indophenol reaction with production of a beautiful greenish-blue dye; with aniline hydrochloride and potassium dichromate, it gives a dark-brown colouration which soon becomes reddish to greenish-brown; it does not give the indamine and saffranine reaction, and in this behaves like a poly-substituted paramidine; when the base is heated with amidoazobenzene, aniline hydrochloride and some free aniline, a reddish-violet melt is obtained, the alcoholic solution of which does not exhibit fluorescence, but appears violet by reflected light, and red by transmitted light.

A characteristic property of octohydro- α -naphthoquinoline is the readiness with which it parts with the added hydrogen atoms of the pyridine nucleus. This takes place when a solution of the base in dilute sulphuric acid is oxidised by means of potassium dichromate; the product is ditetrahydro- α -naphthoquinoline, $C_{26}H_{26}N_2$. It crystallises in white lustrous needles, melting at 282°, and from its reactions appears to be a tertiary base; it does not react with diazo-salts to form dyes.—A. K. M.

A New Class of Fluorescent Dyes of the Quinoxaline Series III. O. Fischer and M. Busch. Ber. 1891, 24, 2679—2683.

The authors have recently shown that the quinoxalines obtained from ketonic alcohols and mono-substituted α -diamines are converted by oxidising agents such as ferric chloride into Witt's phenazonium bases (this Journal, 1891, 998). Thus the triphenyletho- α - β -naphthazonium hydroxide, previously described, has also been obtained by Witt's method from benzil and phenyl-orthonaphthylenediamine.

Diphenyletho- α - β -hydronaphthoquinoxaline—

is obtained by the action of benzoyl carbinol on phenylortho-naphthylenediamine at 150°—160° in a closed tube. It is readily soluble in benzene, less so in ether and in glacial acetic acid, very sparingly in alcohol, and is almost insoluble in light petroleum. Its solutions exhibit an intense yellowish-green fluorescence. It crystallises in lustrous orange coloured needles, melting at 164°—165°. Its solution in concentrated sulphuric acid yields a precipitate of the base when water is added.

In the preparation of the above, a secondary product is also obtained and melts at 194°—196°. It forms magnificent dark red plates which are yellow in reflected light, and its solutions exhibit a purple-red fluorescence.

When the above quinoxaline is oxidised by means of ferric chloride, an azonium compound is produced which is

identical with diphenylethionaphthazonium hydroxide previously prepared from bromacetophenone and β -phenylethionaphthylenediamine (*loc. cit.*).

Methyltriphenylhydroquinoline—

is obtained when benzoin is heated with monomethylorthophenylenediamine for 5–6 hours at 160–170°, and crystallises in bright yellow needles melting at 133°. It is readily soluble in benzene and in ether, less so in alcohol and very sparingly in light petroleum; its solutions exhibit a greenish-yellow fluorescence. Its salts are partially decomposed by water. When the alcoholic solution of the base is heated with ferric chloride and hydrochloric acid, it yields an ammonium base, the ferric chloride double salt of which forms long bright yellow prisms.—A. K. M.

Synthesis of Indigo-disulphonic Acid (Indigo-Carmine).

B. Heymann. Ber. 1891, 24, 3066–3071.

A REPLY to Knietseh, who has offered a different explanation (this Journal, 1891, 916) of the reaction occurring in the synthetic formation of indigo-disulphonic acid from that given by the author (this Journal, 1891, 827), who discovered the method of synthesis.

According to Knietseh, the synthesis of indigo-disulphonic acid from phenylglycine takes place in two stages, leuco-indigotin-disulphonic acid being produced in the first stage, and being oxidised (on diluting the acid solution) by atmospheric oxygen in the second. That atmospheric oxygen takes no part in the reaction, however, the author has now clearly proved, since he finds that, in an atmosphere of carbon dioxide, indigo-disulphonic acid is instantly produced on diluting with concentrated sulphuric acid, the yellow-coloured solution obtained by the action on phenylglycine of fuming sulphuric acid containing 80 per cent. of anhydride. The yellow solution contains the sulphonic acid of indoxyl sulphuric ester, which, as the author has already indicated (*loc. cit.*), is a sulphuric ester of a leuco-indigo compound. This compound, on diluting its solution, is oxidised by the sulphuric anhydride. Several instances of oxidation effected by sulphuric anhydride are cited in support of this view.—E. B.

Examination of the Colouring Matters of the Triphenylmethane Group. E. Noeltling, M. Polonowsky, and Skawinski. Ber. 1891, 24, 3126–3139.

ALREADY abstracted from Bull. Soc. Ind. Mulhouse, 1890, 98–100 (this Journal, 1891, 456–457). See also following abstract.

Dyestuff Derivatives of Triphenylmethane. E. Noeltling and C. Schwartz. Ber. 1891, 24, 3139–3143.

A GREEN dye is formed on oxidation of the quinoline derivative of tetramethyltriamidotriphenylmethane (prepared from tetramethyldiamidobenzhydrol and aniline) (this Journal, 1890, 53). It was assumed that in the latter compound the amido-groups all occupied the para position relatively to the methane-carbon atom, but this has been questioned by Nathansohn and Müller (this Journal, 1889, 978). The compound in question, has, however, been prepared by the present authors from tetramethyldiamidodiphenylmethane (4 parts) by heating with glycerin (3·8), sulphuric acid (6), and nitrobenzene (0·9), 10–12 hours at 110°–150°, as well as by quinylation of the tetramethyltriamidotriphenylmethane obtained by condensation of dimethylaniline and *p*-nitrobenzaldehyde and subsequent reduction. Its constitution must therefore be—

as previously stated (*loc. cit.*)

Tetramethyltriamidodiphenylmethoxytoluylmethane—

was prepared by heating for four hours on the water-bath a mixture of tetramethyldiamidobenzhydrol (10 parts), amido-cresol methyl ether (5·3), and concentrated hydrochloric acid (10·3), pouring the product into water, precipitating with ammonia, and crystallising from alcohol, colourless needles melting at 158°–159° being so obtained. On oxidation of this leuco-base a blue dye is produced; by heating it with acetic anhydride, previously to oxidising, a green dye is formed.

Tetramethyldiamidodiphenylmethoxytoluylmethane—

was prepared from the last-described compound by Skraup's reaction, picric acid being, however, used instead of nitrobenzene as giving a greater yield. The product was obtained from benzene-petroleum in colourless needles melting at 183°, which on oxidation with chloranil or lead dioxide yield a pure-green dye.

It thus appears that quinylation of a para-amido group in triamidotriphenylmethane destroys its influence on the colour of the dyestuff obtainable from the same. (See also this Journal, 1891, 827.)—E. B.

The Condensation of Meldola's Blue with Aromatic and Fatty Amines. C. C. Schlarb. Chem. Zeit. 1891, 15, 1281–1283, and 1317–1318.

THE dyes known as New-blue R, New-blue B, New-blue 2 B, New-blue GB, and New-blue G, representing the products of the interaction of nitrosodimethylaniline hydrochloride, and β -naphthol are not homogeneous compounds, but appear to consist of mixtures in varying proportions of dimethylphenylammonium- β -naphthoxazine chloride (Meldola's blue), the primary product of the reaction, and a dye having a more greenish shade ("cyanamine") which is produced by the condensation of the oxazine chloride with *p*-amido-dimethylaniline, a compound simultaneously formed in the reaction (compare Witt, this Journal, 1890, 933). The oxazine chloride reacts with equal molecules of primary and secondary amines of the aromatic and fatty series yielding greenish-blue dyes for which the author adopts Witt's name "cyanamines" (*loc. cit.*). They are only sparingly soluble in hot and cold water, an addition of mineral acid increasing their solubility in hot water, but are readily soluble in alcohol and organic solvents; they dissolve in mineral acids with a brown colour, are reprecipitated unaltered on diluting with water, and are scarcely attacked by hot concentrated sulphuric acid. On oxidation with potassium bichromate the colour is at first changed to violet, and finally completely destroyed; whilst on reduction leuco-compounds, unstable on exposure to the air, are produced. When the "cyanamines" are precipitated from their solutions by zinc chloride and common salt, they are obtained as tarry masses which dry to hard friable cakes, and on pulverising the latter a brownish-red powder of a feeble coppery lustre is formed; whilst they separate from alcohol in the form of small green needles with a considerable coppery lustre. Cotton mordanted with tannin or tartar emetic decolorises their solutions and assumes greenish-blue shades, which are fast towards light, but in some cases unstable in the presence of alkaline liquids. When the oxazine chloride (Meldola's blue) (5 grms.) is dissolved in 95 per cent. alcohol (250 cc.) in a narrow-necked flask, aniline (1·5 grms.) added, and the flask filled with alcohol and a cork inserted to exclude the air, after remaining for three days the colour is almost pure green, and on removing the cork and passing a current

of air through the liquid, it gradually changes its colour to greenish-blue. It appears therefore that the "cyanamine," which is already formed undergoes an alteration with the oxygen of the air; two atoms of hydrogen are doubtless thus eliminated as water, and its constitution might accordingly be expressed by the formula—

It is difficult, however, to account for the following facts by this formula according to which the formation of the "cyanamine" is independent of the group $=\text{N}(\text{CH}_3)_2\text{Cl}$, contained in the oxazine chloride:—The oxazine chloride is very stable, being only slowly converted into the base by cold aqueous alkalis, whereas the salts of the cyanamine are dissociated even on dilution with water. This remarkable alteration in basicity appears therefore to indicate that in the cyanamine reaction the amido-compound combines with the group $=\text{N}(\text{CH}_3)_2\text{Cl}$ of the oxazine chloride; it would also seem that when air is passed through the product (see above) an atom of oxygen also enters into combination and is then subsequently eliminated together with two atoms of hydrogen as water thus:—

The cyanamines prepared from *m*- and *p*-phenylenediamine, *m*-toluylenediamine, and *p*-amido-dimethylaniline resemble closely the last described compound, but are more readily soluble in hot water, and the shades produced on cotton fibres mordanted with tannin are more stable towards alkaline liquids. To prepare them, New-blue R and the hydrochloride of the diamine (equal mols.) are dissolved in hot water and soda, slowly added to the solution at a temperature of 60° C. until no further precipitation occurs; the precipitate is well washed with acidified water, suspended in dilute hydrochloric acid, and brought into solution by leading a current of steam through, whence the "cyanamine" is reprecipitated from the filtrate by adding zinc chloride and common salt.

Ammonia, dimethylamine and diethylamine are almost without action on New-blue R in aqueous solution, and only indifferent results are obtained when alcohol is used as solvent; the following method yields, however, satisfactory results:—New-blue R is triturated with a solution of copper sulphate (1 part of the salt to 20 parts of the dye), mixed with five times its weight of fine sand, and introduced into a flask of such a capacity that it is three-quarters full; the flask is closed with a treble bored cork and inverted; two tubes, one of which admits air and the other ammonia or the vapour of the amine which is evolved from another flask containing concentrated solutions of ammonia or the diamine, pass almost to the bottom: whilst a third tube connected with an aspirator reaches only a little beyond the cork, and is loosely packed with glass-wool. A drying apparatus is placed between the two flasks. The flask containing the base is heated in such a manner that only a gentle stream of the gaseous compound is evolved, whilst a brisk current of air is aspirated through the liquid; the reaction is usually complete in 3–4 hours. The product is exposed to the air in a thin layer for 2–3 hours, extracted with boiling water, the solution filtered and the dye salted out; the yield of "cyanamine" is 60–90 per cent. of the New-blue R employed. The Ammonia cyanamine may also be prepared by mixing New-blue R (31·5 grms.) to a paste with an equal weight of water at 80° C. until about half the latter has evaporated, and then with 15 cc. of a solution of cupric ammonium sulphate, introducing the mixture into a vessel surrounded with a freezing mixture, and slowly running in (at –10° C.) 10 cc. of a solution of dimethylamine (4·5

grms.). After about two hours the reaction is complete, and the dye is isolated as in the preceding method. The "ammonia cyanamine" is a somewhat strong base, the salts of which are stable in dilute solutions; the shades obtained with it are between blue and greenish-blue.

"Dimethylamine cyanamine" is also obtained in accordance with the equation—

When New-blue R (31 grms.) is mixed into a paste with an equal weight of water at 80° C., and then triturated with dimethylammonium acetate (21 grms.) and lead peroxide (25·9 grms.) at a temperature of 15°–40° for 2–4 hours, the yield is at most 80 per cent. of the New-blue R employed. This dye is the most valuable and beautiful of all the cyanamines; in the pure state it forms bright green needles, and is readily soluble in cold water; alkalis only slowly convert it into the free basis; it dyes cotton mordanted with tannin or tatar-emetic very beautiful fast greenish-blue shades; "diethyl cyanamine" closely resembles the dimethyl-derivative.

It is probable that in the formation of all the "cyanamines" a similar intermediate hydroxy-derivative to that given under "aniline cyanamine" (see above) is produced. "Ammonia cyanamine" is the simplest representative of this series of dyes, the others being substitution derivatives of it; its constitution, according to the author, is—

The value of the cyanamines as dyes will be seen by the following table, which shows their behaviour when boiled with soap and 10 per cent. soda solution respectively:—

Cyanamine of	Soap Solution.	Soda Solution.
Aniline	Brownish-red	Grey.
<i>o</i> -Toluidine	"	"
<i>p</i> -Toluidine	"	"
<i>m</i> -Phenylenediamine	Unaltered	Greenish-grey.
<i>p</i> -Phenylenediamine	"	"
<i>m</i> -Toluylenediamine	"	"

Applications of some New Dyes. H. von Perger. Mittheil. Tech. Gewerbe-Museums, 1891, 202–253.

See under VI., page 30.

Studies on Derivatives of the Toluquinolines and of Metacryloquinoline. E. Noetting and E. Trautmann. Bull. Soc. Ind. Mulhouse, 1891, 285—324.

The two methylquinolines ($\text{CH}_3=1$ and 3) are prepared from *o*- and *p*-toluidine by Skraup's method, the yield being equal to that of the toluidine employed; whilst dimethylquinoline ($\text{CH}_3:\text{CH}_3=1:3$) is prepared from acetyl-*m*-xylydine ($\text{CH}_3:\text{CH}_3:\text{NH}_2=1:3:4$) by the same method; the reaction proceeds much less violently than when the free xylydine is employed. When quinoline is dissolved in sulphuric acid (10 parts) and to the cool solution nitric acid (1 mol.) mixed with sulphuric acid is added, afterwards sufficient of 20—25 per cent. fuming sulphuric acid to remove the water present, kept for some days in the cold, and finally heated on the water-bath, 4-nitroquinoline is formed (compare Koenigs, Ber. 12, 113; Claus and Kramer, Ber. 18, 1243).

4-Nitro-3-methylquinoline is obtained by treating 3-methylquinoline dissolved in sulphuric acid (5 parts) with the calculated quantity of nitric acid of sp. gr. 1.39, mixed with three times its weight of sulphuric acid at 100°; the quantity of sulphuric acid used and the temperature at which the reaction takes place appear, however, to have no influence on the nature of the product. It crystallises from alcohol in small bright yellow needles and melts at 116°—117°; the *methiodide* melts at 189—190°; the corresponding *amido-derivative* melts at 145°, and gives an *acetyl-compound* melting at 160°; the *hydroxy-derivative*—

obtained from the amido-compound by the diazo-reaction sublimes in colourless needles and melts at 230°; is insoluble in cold water and not volatile with steam. On treating 3-methylquinoline with 25 per cent. fuming sulphuric acid at 90° a sulphonic acid is produced which yields the last-mentioned hydroxy-derivative on fusion with potash. *Methylquinolinequinone oxime*—

prepared by dissolving 4-hydroxy-3-methylquinoline in concentrated hydrochloric acid (2.5—3.5 mols.), cooling to 0°, adding sodium nitrate (1 mol.) and precipitating with sodium acetate, separates from alcohol in yellowish luminae decomposing without melting above 200°; it dyes cotton mordanted with iron a beautiful bright fast green. The latter property appears to be in opposition to Kostanecki's observation (this Journal, 1889, 698), namely, that only *o*-quinone-oximes colour mordanted fibres. Attention is drawn to the fact, however, that quinoline is a weak chromogen, and it has already been mentioned (this Journal, 1891, 356) that 1-hydroxyquinoline colours mordanted fibres; this may also be said of the higher homologues of the latter (see below), whilst it is not the case with those hydroxyquinolines, containing the hydroxyl-group in any other position, even carbostyryl belonging to the latter class. The quinone-oxime-derivatives of quinoline colour mordanted fibres when they are derivatives of an *o*-quinone, but not when they are derivatives of a *p*-quinone, unless a chromophoric group occupies simultaneously the position 1 (peri-position); thus of the two compounds—

the second only possesses tinctorial properties.

1-Nitro-3-methyl-4-hydroxyquinoline, obtained by oxidising the corresponding quinone oxime with potassium ferriyanide, forms salts with acids and bases, but is not a dye.

1-Hydroxy-2-methylquinoline, prepared from amidocresol ($\text{NH}_2:\text{OH}:\text{CH}_3=1:2:3$), crystallises from dilute alcohol in long colourless needles, melts at 72°—74°, is volatile with

steam, and gives a green colour with ferric chloride; it dyes mordanted cotton, and when heated with copper oxide in the Bunsen flame imparts a colour to the latter resembling that produced by the halogens, a property which 1-hydroxyquinoline and its other methyl-derivatives also possess.

The *quinone-oxime*—

formed by treating the last described hydroxy-derivative dissolved in acetic acid with sodium nitrite (1 mol.), is not a dye, but 1-hydroxy-2-methyl-4-nitroquinoline obtained by oxidising it with potassium ferriyanide colours cotton mordanted with alumina, yellow, or with iron, brown.

1-Hydroxy-4-methylquinoline, obtained from amido-cresol ($\text{NH}_2:\text{OH}:\text{CH}_3=1:2:5$) crystallises from dilute alcohol in colourless needles, melts at 122°—124°, and dyes yellow with alumina mordants; the *quinone-oxime*—

dyes green with iron mordant, and yields a *nitro-compound*—

melting at 205—206°, which dyes yellow with alumina and brown with iron mordants.

4-Nitro-3-methylquinoline, melting at 116—117° (see above) represents the chief portion of the product from nitrotoluidine ($\text{CH}_3:\text{NH}_2:\text{NO}_2=1:4:6$.)

1-Nitro-3-methylquinoline, prepared from nitro toluidine ($\text{CH}_3:\text{NH}_2:\text{NO}_2=1:4:5$.) yields on reduction with sulphuretted hydrogen in ammoniacal alcoholic solution, the corresponding *amido-derivative*, which melts at 62°—64°, yields an *acetyl-derivative* melting at 91°—92°, and the corresponding hydroxy-derivative by the diazo-reaction. The *quinone-oxime*—

which colours mordanted fibres is obtained from the last-mentioned amido-derivative. 1-Amido-4-chloro-3-methylquinoline is formed, together with the non-chlorinated base (see above), when the nitro-methylquinoline is reduced with tin and hydrochloric acid; it crystallises from alcohol in pale yellow needles, melts at 129°—130°, and yields an *acetyl-derivative* melting at 136°—137°.

4-Nitro-1-methylquinoline, obtained by nitrating 1-methylquinoline with a mixture of nitric and sulphuric acid, or from nitro toluidine ($\text{CH}_3:\text{NH}_2:\text{NO}_2=1:3:5$) by Skraup's method, forms transparent yellow needles, melts at 93°, and gives a purple liquid rapidly becoming red on heating with alcoholic potash; the *amido-derivative* crystallising from dilute alcohol in long yellowish needles, and melting at 143°, is furnished on reduction with iron and acetic acid; the latter gives Skraup and Fischer's methylphenanthroline melting at 95°—96° when treated by Skraup's method; it also yields an *acetyl derivative* melting at 187°, and the corresponding hydroxymethylquinoline melting at 262°—263° by the diazo reaction. The *quinone-oxime*—

produced by treating the hydroxy-derivative dissolved in glacial acetic acid with sodium nitrite (1 mol.) decomposes above 200° without melting, gives insoluble lakes with the heavy metals, and colours fibres, mordanted with iron, green; the nitro-derivative—

formed by oxidising the quinone-oxime with potassium ferriyanide melts at 181°—182°, and does not colour mordanted fibres.

When 4-nitro-1-methylquinoline (12 grms.) is dissolved in a mixture of concentrated hydrochloric acid (40 cc.) and water (100 cc.) iron filings (10 grms.) being then added in small portions at a time, a red substance separates, which is

purified by repeated recrystallisation from hydrochloric acid, and is finally treated with ammonia and crystallised from glacial acetic acid, from which it separates in orange needles melting at 260°; this is found to be the *azomethylquinoline*—

the corresponding azoxy-derivative is obtained on adding ammonia to the united hydrochloric acid mother-liquors from the azo-compound, and extracting the precipitated compound with boiling alcohol, but it is best obtained by dissolving the nitromethylquinoline in a mixture of water (100 cc.) and concentrated hydrochloric acid (40 cc.) and slowly adding iron filings (6 grms.) with agitation; the pure substance melts at 201°, and gives the hydroxy-azo-derivative on heating at 110°–115° with concentrated sulphuric acid (10 parts).

1-Nitro-1 : 3-dimethylquinoline is obtained by dissolving 1 : 3-dimethylquinoline in concentrated sulphuric acid (200 grms.), adding a mixture of nitric acid of sp. gr. 1.39 (23 cc.) and concentrated sulphuric acid (50 cc.) and finally heating on the water-bath, or by treating nitroxyline $[(\text{CH}_3)_2\text{NH}_2 \cdot \text{NO}]_2 = 1 : 3 : 4 : 6$ according to Skraup's method; it crystallises from alcohol in long yellowish needles and melts at 107°–108°. The *amido-derivative* produced on reducing the preceding either with iron and acetic acid or with tin and hydrochloric acid, melts at 91°, and gives an *acetyl-compound* melting at 201°.

1-Hydroxy-1 : 3-dimethylquinoline is obtained from the amido-derivative by the diazo-reaction; it crystallises from chloroform in white tablets, sublimes in small needles without decomposition, and melts at 197°–198°.—A. R. L.

Metaxylenesulphonic Acids (II). G. T. Moody. Proc. Chem. Soc. 1891–1892, 189–190.

In a previous communication (Proc. 1888, 77), the author has described the preparation of 1 : 2 : 3-metaxylenesulphonic acid, and has called attention to the fact that only the 1 : 3 : 4-acid is formed on direct sulphonation of the pure hydrocarbon. Attempts to prepare the symmetrical 1 : 3 : 5-sulphonic acid have not yet met with success, the sulphonation of 1 : 3 : 4-acetmetaxylid failing to give the required substitution.

Acetmetaxylid (1 : 3 : 4) is readily sulphonated when heated for some time at 140° with $\frac{1}{2}$ times its weight of 20 per cent. anhydrosulphuric acid, and on boiling the solution after the addition of water, metaxylidine sulphonic acid $[\text{CH}_3 : \text{CH}_3 : \text{NH}_2 : \text{SO}_3\text{H} = 1 : 3 : 4 : 6]$ is obtained. It crystallises from water, in which it is only very sparingly soluble, in well-formed, slender needles, insoluble in alcohol and other common solvents; it does not change at 290°, and when heated to a higher temperature decomposes without having previously melted. The sodium salt, $\text{C}_6\text{H}_3\text{Me}_2\text{NH}_2\text{SO}_3\text{Na} \cdot \text{H}_2\text{O}$, is exceedingly soluble in water and crystallises in flat plates.

When the diazo-product is boiled with bromhydric acid, the corresponding bromoxyline sulphonic acid $[\text{CH}_3 : \text{CH}_3 : \text{Br} : \text{SO}_3\text{H} = 1 : 3 : 4 : 6]$ is formed. It crystallises in long, slender needles, and does not melt at 270°, but at a considerably higher temperature melts with decomposition. The sodium salt agrees with the description given by Weinberg (Ber. 11, 1062), who obtained it on bromination of a dilute aqueous solution of barium 1 : 3 : 4-metaxylenesulphonate; but the sulphochloride obtained by the author, which crystallises in splendid, oblique prisms, melts at 2° higher (62–63°), whilst the sulphonamide melts at 5° lower (189°) than found by Weinberg. The melting point of the sulphonamide agrees with that given by Sartig (Annalen, 230, 335), who prepared it by sulphonating metaxylidine, and subsequently replacing amidogen by bromine. It thus appears that both xylidine and acetxylid give the same acid on sulphonation, and that the displacement of hydrogen in the amido-group by acetyl does not lead to any change in the position taken up by the sulphonic group.

PATENTS.

Improvements in the Manufacture of Di-alkyl-meta-amido-cresols. H. H. Lake, London. From "A. Leonhardt and Co.," Muhlheim, Germany. Eng. Pat. 20,252, December 11, 1890. 6d.

DIMETHYL- and diethyl-meta-amido-cresols can be produced by diazotising the corresponding meta-amido-dialkyl-orthotoluidines and then decomposing the diazo-compounds with water, or by sulphonating the dialkyl-orthotoluidines and fusing the resulting sulphonic acids with alkalis at a high temperature. The meta-amido-dialkyl-orthotoluidines can be obtained by nitrating the dialkyl-orthotoluidines in sulphuric acid solution and then reducing the mono-nitro-compound thus formed. Details for the preparation of dimethyl-meta-amido-cresol from meta-amido-dimethyl-orthotoluidine and of the di-ethyl compound from di-ethyl-orthotoluidine are given in the specification. The former distils without decomposition and can be crystallised from a mixture of benzene and petroleum spirit; it melts at 76°, and dissolves readily both in caustic alkalis and in mineral acids. The latter is a thick oil boiling at 264°–267° C. Both products are of value in the colour industry in cases where the di-alkyl-meta-amidophenols are of less or no value, as, for instance, in the production of the blue basic dyestuffs obtained with the nitroso-derivatives of the aromatic amines (Eng. Pat. 13,565 of 1890; this Journal, 1890, 760).

The formula of the dimethyl compound is probably—

—C. A. K.

Improvements in the Manufacture of Indigo-carmin from Phenyl-glyceoll and its Salts or Ethers. B. Wilcox, London. From the "Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 20,563, December 17, 1890. 6d.

By treating phenyl-glyceoll, its salts or ethers with fuming sulphuric acid at a low temperature, pouring into concentrated sulphuric acid, and subsequently diluting the solution with concentrated sulphuric acid, the phenyl-glyceoll is easily converted into indigo-carmin. The process is in fact an application of that described in Eng. Pat. 12,715 of 1890 (this Journal, 1891, 759). One kilo. of phenyl-glyceoll is mixed with 20 kilos. of dry pure sand and added to 20 kilos. of sulphuric acid containing 80 per cent. of anhydride, the temperature not being allowed to rise above 30° C. The yellow liquid thus obtained is mixed with sufficient sulphuric acid of 60° B. to convert all the sulphuric anhydride in excess into sulphuric acid. This produces a liquid of an intense blue colour, which is poured on to ice and the indigo-carmin formed salted out. The excess of anhydride can also be removed by passing moist air through the melt, but the conversion is slower than by the method above described.—T. A. L.

Improvements in Triphenylmethane Colouring Matters. S. Pitt, Sutton. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 857, January 16, 1891. 6d.

VIOLET and blue colouring matters which are sulphonated derivatives of secondary and tertiary rosanilines are obtained by oxidising certain derivatives of diamidodiphenylmethane in presence of an aromatic amine, such as dimethylaniline or diphenylamine, in an aqueous or alcoholic solution. The following example illustrates the formation of a violet dyestuff:—Di-ethylidibenzyl-diamido-diphenylmethane disulphonic acid is prepared by heating 58 kilos. of ethyl benzyl aniline sulphonic acid with a concentrated aqueous solution of 3 kilos. of formic aldehyde on the water-bath for 12–24 hours. The solution is made alkaline with caustic soda and the sodium salt of the acid precipitated by salt. 60 kilos. of this acid are then dissolved in 1,000

litres of water and heated for 25 hours to 30—40° C. with 12 kilos. of dimethylaniline and 20 kilos. of potassium bichromate. After filtration, the disulphonate of the diethyl-dimethyl-dibenzyl-triamidotriphenylearbinol is salted out from the violet solution. The formation of this body may also be performed in one operation by mixing the solutions of ethyl-benzylaniline sulphonic acid (3 mols.), formic aldehyde (1 mol.), with the oxidising agent and heating for some time.—T. A. L.

Improvements in the Production of a Blue-Green and a Red-Violet Colouring Matter from Alizarin Blue. O. Imray, London. From the "Farbwerke vormals Meister, Lucius und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 1354, January 24, 1891. 6d.

By acting with nitrosulphuric acid (containing sulphuric anhydride) on Alizarin blue a Nitro-alizarin blue can be obtained which on reduction yields an Amido-alizarin blue, both of which substances are very strong colouring matters. One kilo. of finely-powdered Alizarin blue is added, at 6° C., to 1.5 kilos. of nitric acid of 47° B. and 4.5 kilos. of sulphuric acid containing 20 per cent. of sulphuric anhydride, and the whole slowly heated to 20° C. When a sample, precipitated by water, washed and redissolved in sulphuric acid, does not show the characteristic spectrum of Alizarin blue, the melt is poured into a dilute soda solution, cooled with ice, and the sodium salt which separates is decomposed with an acid. The Nitro-alizarin blue forms a greenish-blue powder which crystallises from naphtha in fine scales. It may be used for dyeing and printing by itself or together with bisulphite. The conversion into the amido compound is performed as follows:—One kilo. of Nitro-alizarin blue is suspended in 50 litres of water containing 2.5 kilos. of a 35 per cent. caustic soda solution and 8 kilos. of glucose, and the whole heated to 70°—80° C. until a sample, decomposed by an acid, filtered and washed, dissolves in ammonia with a pure blue colour. The whole solution is then acidulated, and the amido compound formed filtered off and washed. In place of the glucose other alkaline reducing agents may be employed. The Amido-alizarin blue is a reddish-violet colouring matter twice as strong as Alizarin blue. It can be used for dyeing and printing similarly to the nitro compound.—T. A. L.

Improvements in the Manufacture of Colouring Matters. O. Imray, London. From the "Actien Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 1737, January 30, 1891. 6d.

A RED colouring matter which dyes wool and cotton is obtained by reacting with the intermediate product, formed by combining one molecule of diazotised benzidine with one molecule of β -naphthol disulphonic acid G (Eng. Pat. 2213 of 1886; this Journal, 1891, 133), on the methyl, ethyl, and phenyl ethers of salicylic acid, or on *o*- and *m*-cresol carboxylic acid. These colouring matters may afterwards be converted into their methyl or ethyl derivatives, giving somewhat similar shades. The alkylated dyestuffs, however, resist the action of alkalis, and may thus be dyed from an alkaline or soap bath.—T. A. L.

The Manufacture of New Dyestuffs derived from Anthracene and Anthraquinone. B. Wilcox, London. From the "Farbenfabriken vormals Fr. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 1883, February 2, 1891. 6d.

THE first part of this patent is an extension of Eng. Pat. 18,729 of 1890 (this Journal, 1891, 917), and describes the application of the process to dichloro- or dibromo-anthracene in place of the anthraquinone there employed. The specification then describes the sulphonation of "Alizarin-eyanine G" obtained according to Eng. Pat. 17,712 of 1890 (this Journal, 1891, 917). Another claim refers to the sulphonation of colouring matters obtained according to Eng. Pat. 12,715 of 1890 (this Journal, 1891, 759).

—T. A. L.

A New or Improved Material for Use in the Production of Colouring Matters. I. Levinstein, Manchester. Eng. Pat. 2682, February 14, 1891. 6d.

ACCORDING to this invention a new naphthylamine disulphonic acid is obtained in the following manner:—100 lb. of sodium α -naphthalene sulphonate are quickly stirred into 300 lb. of concentrated sulphuric acid previously heated to 150° C., and the mixture is kept at this temperature for 2—4 hours, forming a naphthalene disulphonic acid. After cooling to 10°—15° C., 45 lb. of nitric acid of 40° B. are run in, the temperature being kept below 40° C. The whole is then poured into 700 lb. of brine, when the new nitro-naphthalene disulphonic acid separates out. After washing with brine and pressing, the acid is dissolved in 400 lb. of water and reduced by boiling with 50 lb. of iron borings. When the reduction is complete, the mixture is made alkaline with soda, filtered, concentrated, and allowed to crystallise. The sodium salt of the new naphthylamine disulphonic acid thus obtained is filtered off, pressed, and dried. The same naphthalene disulphonic acid as above described is said to be obtained by stirring 60 lb. of naphthalene into 240 lb. of cold concentrated sulphuric acid and agitating the mixture until a sample dissolves in cold water. The whole is then heated with the addition of anhydrous sodium sulphate to 150—160° C. for 2—4 hours, or as long as may be necessary. The subsequent treatment is the same as above.—T. A. L.

Improvements in the Manufacture and Production of Colouring Matters. C. Dreyfus, Manchester. Eng. Pat. 17,635, October 15, 1891. 4d.

A PROCESS for preparing lakes from basic coal-tar dyes by precipitating the latter in presence of a neutral resin soap by means of a soluble metallic salt or of a salt of an alkaline earth. The lakes are soluble in benzene, "solvent naphtha," alcohol, ether, carbon bisulphide, chloroform, oleic and stearic acids, linseed oil, turpentine, &c., but are insoluble in petroleum and glycerol. They can be used for printing inks, paints, and also as paper-staining colours. (See also Eng. Pat. 2878 of 1886; this Journal, 1887, 138.)

Note on the Scouring of Wool of different Growths. J. J. Armandon. Monit. Scient. 1891, 1256—1263.

THIS paper contains a long list showing the percentages of suint, water, and scoured wool (dried at 100°) in 40 kinds of wool. All these wools are now on exhibition at the "Musée Méreologique" at Turin. The method of analysis employed is as follows:—500 grms. of wool are taken and treated with water rendered slightly alkaline. To 10 litres of water 200 to 250 grms. of soda crystals are added, and for each 100 grms. of wool 2 litres of water, containing about 50 grms. of soda crystals, are used. The wool is allowed to soak for three hours, agitating from time to time, at a temperature of from 60°—70°. It is then taken out and washed with water until the wash-water is clear. The wool is then pressed and dried upon a stretched linen cloth exposed to a current of air. After 20 days' exposure to the air and sun it is weighed and the drying is then continued until the weight remains constant. The loss of weight gives the suint plus the water lost by drying in air. A small portion of the wool is then dried at 100°, and the loss of weight noted.—H. S. P.

PATENT.

Production from Mineral Oils of Sulphonic Acids and Sulphones, and the Manufacture of a New Product by Treating Gelatinous Matter with Sulphonic Acid. A. M. Clark, London. From the "Gewerkschaft Messel," Grube Messel, Germany. Eng. Pat. 19,502, November 29, 1890, 6d.

Use of Sodium Tungstate as a Fixing Agent for Mordants. G. Ulrich. Mittheil. Techn. Gewerbe-Museums, 1891, 187—195.

THE employment of a 15 per cent. solution of sodium tungstate is recommended for fixing chromium, aluminium, tin, iron, nickel, cobalt, and similar mordants on yarns or fabrics composed of cotton, wool, or silk, or of mixtures of two different fibres. The material to be mordanted is impregnated with a solution of chromium acetate, basic aluminium sulphate, &c., and passed (in the case of cotton fabrics, preferably after drying) through the sodium tungstate bath, which is heated to 30°—40°. The mordants, which are fixed in the form of tungstates, give on dyeing shades which in point of brilliancy and fastness compare well with those obtained on the free metallic oxides. The cotton in a mixed fabric should be prepared with oleum before weaving, to ensure a regular deposition of the mordant on the fabric. This application of sodium tungstate has been patented in Germany (Ger. Pat. 58,171 of 1890).—E. B.

Experiments in Mordanting Wool with Iron. G. Ulrich. Mittheil. Techn. Gewerbe-Museums, 1891, 195—196.

Wool mordanted with cream of tartar (1 mol. per mol. of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$) and ferrous sulphate dyes a dull grey-black with logwood. An addition of copper sulphate to the mordanting bath effects a marked improvement in the shade of black produced. The best results are obtained with 10 per cent. (of the weight of the wool) of ferrous sulphate, 8.15 of cream of tartar, and 3.6 of copper sulphate.

Also with the ferric mordant copper sulphate is found to be a useful addition. A rich black is obtained on dyeing with logwood wool which has been mordanted with iron alum (12 per cent.), cream of tartar (6 mols. per mol. of iron alum), and copper sulphate (4 mols.).

The logwood blacks dyed on the mixed copper-iron mordant are faster to light than those obtained on the iron mordant alone.—E. B.

Application of Alizarin Lakes for Colouring Candles, &c. G. Ulrich. Mittheil. Techn. Gewerbe-Museums, 1891, 198—202.

See under XII., page 44.

Applications of some New Dyes. H. von Perger. Mittheil. Techn. Gewerbe-Museums, 1891, 202—253.

Fast Green, blue shade (alkaline salt of sulphonated benzyltri- or benzyltetra-alkylated pararosaniline), is sold both as powder and paste, the latter a 10 per cent. solution in acetic acid. It dyes wool and silk a dark blue-green from an acid bath, the shades being fuller and faster than those yielded by Acid green. Concentrated sulphuric acid dissolves the dye with a golden-brown colour.

Acridine Orange (Eng. Pat. 8243 of 1890; this Journal, 1891, 537), is dyed or printed on cotton with tannic acid as mordant.

Pyronine (Eng. Pat. 13,217 of 1889; this Journal, 1890, 931) dyes silk, wool, or tannin-mordanted cotton a pink resembling Rhodamine.

Toluylene Blue, (Eng. Pat. 2499 of 1890; this Journal, 1891, 132) a basic induline-dye prepared by the action of *p*-phenylenediamine on the induline-base of the formula $\text{C}_{30}\text{H}_{27}\text{N}_3$, gives on cotton mordanted with tannic acid dark shades of blue resembling indigo; alum and chromium acetate are added to the dye-bath, and the dyed cotton is passed through a boiling solution of potassium bichromate to darken the shade. The blue may also be dyed on unmordanted cotton from a bath containing acetic acid and sodium acetate. It is also suitable for wool and silk. It dissolves in concentrated sulphuric acid with a blue colour; alkalis precipitate the colour base; potassium bichromate gives a blue-black precipitate.

Rosinduline 2 B is the sodium salt of a rosindulone sulphonic acid (this Journal, 1890, 601); it dyes wool bluish-red from an acid bath; in applying it copper dye-vessels must be avoided. The dye is tolerably fast to light, but not so to soap. Of similar composition to this dye is *Rosinduline 2 G*, which is applied in a similar way, yielding scarlet shades. This dye exhibits on silk an orange-red fluorescence. Its fastness to light is inferior to that of the 2 B quality.

1-Naphthyl Blue, anilido-isonaphthylrosinduline, is obtained, together with phenylrosinduline by the action of phenylazo- α -naphthylamine on aniline. Silk which has been dyed with it shows a red fluorescence. It is faster to light than the indulines in ordinary use. Its blue-green solution in concentrated sulphuric acid turns successively blue and blue-purple on dilution with water.

Azine Green (Eng. Pat. 3098 of 1890; this Journal, 1891, 132) is dyed on cotton by means of tannic acid, and is very fast towards dilute solutions of alkalis, acids, and bleaching powder.

Thiocarmine R is produced by the oxidation of a mixture of ethylsulphobenzyl-*p*-phenylenediaminethiosulphonic and ethylbenzylanilinesulphonic acids, and has the formula—

It is sold in the form of paste, which is employed for dyeing wool with the addition to the dye-bath of sodium sulphate and sulphuric acid. The blue shades produced are not fast to light. Concentrated sulphuric acid dissolves the dye with a green colour; acidulated stannous chloride decolourises it.

Toluidine Blue is the sulphate of trimethylthionine—

It is applied in the same way as Methylene blue, which it resembles.

Methylene Green extra, the mononitro derivative of Methylene blue, is prepared from the latter substance by dissolving it in concentrated sulphuric acid, cooling to 0°, and adding the calculated quantity of sodium nitrite. It is faster to bleaching powder solution than Methylene blue, and also even faster to light than that dye. It colours concentrated sulphuric acid blue-green; alkalis yield a purple precipitate; acidulated stannous chloride decolourises it, the colour being restored by hydrogen dioxide.

Methylene Grey is a mixture of several dyes.

Nitrazine Yellow is manufactured by heating nitroxylylhydrazinesulphonic acid with dihydroxytartaric acid. It dyes silk and wool a more greenish shade of yellow than Tartrazin S, and on wool is faster to milling than the latter. It may be distinguished from the latter dye by the greater solubility of its barium compound, Nitrazine yellow not being precipitated by the addition of barium chloride to its hot aqueous solution.

Azo-green, prepared by diazotising *m*-amidotetramethyldiamidotriphenylcarbinol and combining the resultant compound with salicylic acid (Eng. Pat. 3398 of 1890; this Journal, 1891, 249), comes into commerce in the form of a paste, which dissolves in water with a green colour and in concentrated sulphuric acid with a brown. It may be fixed on cotton by means of tannic acid, and on wool on the chrome mordant. It is also recommended for calico-printing in conjunction with chromium acetate as a mordanting salt. Its fastness to light and soaping or milling is, however, scarcely satisfactory.

Anthracite Black—

is obtained from a naphthylaminedisulphonic acid by diazotisation and combination with naphthylamine and combination of the diazo derivative of the resultant compound with dibazyl-*m*-phenylenediamine (Eng. Pat. 4825 of 1889; this Journal, 1890, 172). It dyes wool directly with 4 per cent. of dyestuff a blue-black, which is fast to light but only moderately so to milling.

Chromotropes of the shade-marks 2 R, 2 B, 6 R, 8 B, and 10 B, are azo-dyes, which have the property, when dyed in the customary manner on wool (yielding shades ranging from scarlet to violet-red) of being transformed by the action of a boiling solution of potassium bichromate into blue-black, black, or green-black colours, whose fastness to light and milling is very considerable.—E. B.

The Dyeing of Black Hosiery. E. Frey. *Färber-Zeitung*, 1891, 53—54.

COTTON stockings and knitted goods are now generally dyed black with aniline, and the author describes the process as applied to stockings. The goods are first boiled for one hour with from 3 to 5 per cent. of their weight of soda in water, and then rinsed and soaked for half an hour in water at 40° C. containing from 5 to 10 per cent. of their weight of acetic acid. The goods are taken out of this bath, drained, and dried in a room maintained at 40° to 50° R. (50°—60° C.), when they are ready for dyeing. Two solutions are used for the dyeing process. The first is made by mixing 15 kilos. each of aniline salt, aniline oil of 4, and hydrochloric acid of 18 B. When cold, this mixture is added

to 50 litres of water containing 15 kilos. of sodium chloride. The second solution is made by dissolving 5 kilos. of copper sulphate, 100 grms. of sodium bichromate, and 500 grms. of concentrated sulphuric acid in sufficient water to bring the density to 4° B. A wooden trough is filled with the first solution diluted with water to a density of 8° B., and one litre of the second or copper solution is added and well mixed. The dry stockings are then immersed and well stirred about in the bath for half an hour, when they are taken out and drained, first on a rack and finally in a centrifugal machine. Each stocking is then drawn over a leg-shaped board, on which it is carefully smoothed out, and is placed in the oxidation chamber, where it is exposed to moist air at 45° R. (56° C.) for two hours. The stockings, now of a dark green colour, are taken off the boards and worked for a quarter of an hour at 30° R. (37° C.) in a solution of 3 per cent. of potassium bichromate, which fully develops the black colour. The goods are then rinsed and well washed in a washing-machine charged with 10 per cent. of oleme soap, 2 per cent. of soda, and 2 per cent. of ammonia, and after 40 minutes' treatment at 40° R. (50° C.) they are rinsed in water and dried.—G. H. B.

See under XIX., pages 52—55.

Applications of New Insoluble Azo Colouring Matters for Cotton Dyeing. A. Kertész. *Chem. Zeit.* 1891, 15, 701—702.

BEFORE the discovery of primuline the results obtained were more or less unsatisfactory, as no method of this kind existed for rendering dyes on cotton fast. Primuline contains a free amido-group which, if diazotised on the fibres, produces perfectly insoluble and fast dyes. L. Cassella and Co. are known to have prepared certain colouring matters, by treating benzidine and its analogous compounds with γ -amidonaphtholsulphonic acid, and it is interesting to note that the azo derivatives of this acid contain a free amido-group; it may, therefore, be expected that these will show the same property as primuline. This is actually the case, as Baeyer has proved, and the following colouring matters can be diazotised on the fibres: Diamine black RO, Diamine black BO, Diamine blue-black E, which, if developed with different substances, give indigo blue, dark blue, or blackish shades respectively, and Diamine brown V.

To these must be added Cotton-brown A and Cotton-brown N, which were known for some time previously.

The process of diazotising is an expeditious one, e.g., cotton treated with Diamine black and passed through the acid nitrite bath, at once changed to a light blue. In many instances it is advisable to wash the material after the diazotising process. Then follows the development by means of amido- or oxy-compounds. Experiments show that the best developers are β -naphthol for dark blue shades; naphthylamine ether for indigo blue; phenylenediamine or resorcinol for black; and Chrysoidine AG for brown. The developing baths are prepared in the following way:—

(1.) *β -Naphthol.*—1,450 grms. of β -naphthol and 1,200 grms. of caustic soda (40°) are dissolved in hot water and diluted to 20 litres. One-tenth litre of this solution is required for every kilo. of cotton, and at the beginning 2 litres have to be added for every 100 litres of water.

(2.) *Naphthylamine ether.*—The paste has to be dissolved in boiling water. Fifty grms. of paste are required for every kilo. of cotton, and at the beginning 1 kilo. of paste must be added for every 100 litres of water.

3. *Phenylenediamine.*—1,080 grms. of phenylenediamine are dissolved in 20 litres of hot water, the same quantities being used as of the β -naphthol solution.

(4.) *Resorcinol.*—1,100 grms. of resorcinol and 2,400 grms. of caustic soda (40°) must be dissolved and diluted to 20 litres, the same proportions being employed as for the β -naphthol solution.

(5.) *Chrysoidine AG*.—Four grms. of Chrysoidine AG (dissolved in hot water) are required for every kilo. of cotton; and at the beginning 10 grms. for every 100 litres of water. To keep the bath neutral, chalk is added at the rate of 5 grms. for every kilo. of cotton.

The diazotised materials are passed through the cold developing liquids for about 10 or 15 minutes, and then washed with water, or with water and soap. (Compare this Journal, 1891, 762—763.)—H. S.

Method for the Valuation of Extracts of Logwood.
v. Cochenhausen. Monit. Scient. 1891, 5, 943—948.

Up to the present, according to the author, there has existed no analytical method for the determination of colouring matters in extracts. If the oxidation of hæmatoxylin does not stop at hæmatein there is no reason why [extract of logwood should not contain all the possible oxidation products. Very little is known as to the functions of hæmatoxylin, hæmatein, and their further oxidation products in dyeing, and it is with the object of elucidating these points that the author has made the following experiments. (Compare this Journal, 1889, 612—618.)

Pure hæmatoxylin and hæmatein were employed in solutions of 0.5 per cent., except when otherwise stated. The percentages of dye and mordant refer to pounds of fibre dyed. The wool employed was mordanted (1) with 4 per cent. of commercial chromium fluoride and 4 per cent. of tartar; (2) with 1 per cent. of potassium dichromate and 0.33 per cent. of sulphuric acid; (3) with 1 per cent. of potassium dichromate and 2 per cent. of tartar; (4) with 6 per cent. of alum and 4 per cent. of tartar. The cotton was mordanted as usual with iron, strong and weak, with alumina, strong and weak, and with a mixture of iron and alumina. Some of the pieces were mordanted with 3 per cent. of tannin and a solution of aluminium acetate at 5° B. The dyeing operation lasted for one hour.

The results of dyeing wool and cotton mordanted as above in hæmatoxylin solution were the same; in both cases the samples mordanted with chromates were immediately dyed blue, while those mordanted with chromium oxide and alumina were not dyed at all during the first 20 minutes, and at the end of the hour only a much feeble shade than that obtained with the chromic acid mordants. When these experiments are conducted in vessels which yield alkali to boiling water, or with water which contains chalk or dissolved air, the shades obtained are totally different.

With hæmatein all samples, whether mordanted with chromium oxide or chromic acid, give the same colours.

The dyeing by hæmatoxylin of chromic acid mordanted fabrics is, then, due to the oxidation of the hæmatoxylin to

hæmatein by the chromic acid. The iron mordanted cotton dyed the same in both baths, apparently because of the oxidising action of ferric oxide on hæmatoxylin.

Inasmuch as hæmatein is capable of further oxidation to substances which have little tinctorial value, it might be expected that the more chromic acid is put into a fabric the less dyed it will be by hæmatein. Experiments showed that this is actually the case; when 6 per cent. of potassium dichromate and 2 per cent. of sulphuric acid were used, hæmatoxylin (5 per cent. solution) produced no colour in the fabric. Further experiments showed that this oxidation rapidly deteriorates an alkaline bath of hæmatoxylin, the hæmatein at first formed soon becoming further oxidised.

Dyers prefer decoctions to extracts of logwood; this is probably because the former, especially when made from fermented wood, contain more hæmatein and less foreign substances: for when wool is mordanted with potassium dichromate and acid, even if tartar be not present—and owing to its high price it is frequently omitted—some of the chromic acid gets reduced either by organic matter in the water or by the wool itself. When hæmatein is present it immediately forms a lake with the chromium oxide, while the remaining chromic acid is oxidising hæmatoxylin. When, however, only hæmatoxylin is present it has to be oxidised by the chromic acid, the chromium oxide meantime dulling the shade by combining with the foreign matters.

The author dismisses the methods of Houzeau (Dingl. Polyt. J. 190, 242) and Schreiner (this Journal, 1890, 976) for the valuation of logwood extract as being inexact, and adopts a comparative method in which a series of samples, mordanted according to a fixed prescription, are dyed with the extract to be valued and compared with the same series dyed with standard solutions of hæmatoxylin and hæmatein, arranged in diminishing arithmetical progression, viz.:—

0.5 per cent., 0.45 per cent., 0.4 per cent., 0.35 per cent., 0.3 per cent., 0.25 per cent. (*sic*), 0.2 per cent., 0.15 per cent., 0.1 per cent., 0.05 per cent.

The series of shades are obtained with the following wools:—(1), mordanted with 4 per cent. of chromium fluoride and 4 per cent. of tartar, and dyed in hæmatein; (2), mordanted with 1 per cent. potassium dichromate and 2 per cent. of tartar, and dyed with hæmatoxylin; (3), mordanted with 6 per cent. alum and 4 per cent. tartar, and dyed with hæmatein.

As hæmatoxylin gives a feeble tint to chromium oxide mordanted wool, 0.05 per cent. of hæmatein is allowed for this shade on such wool, while 0.025 per cent. is allowed for alum-mordanted wool.

The following table gives some of the author's results; the numbers in brackets indicate the hæmatein which would have been present in the original extract if that fixed by the wool be supposed to have been so present:—

	Source.	Price per 100 Kilos.	Hæmatein.	Hæmatoxylin.	Price per 100 Kilos. of Colouring Matter.
			Per Cent.	Per Cent.	
1. Logwood extract, NyD. solid.....	America	Sch. 96	— (2.5)	90	240
2. Sanford extract, solid	America	?	Trace (3.75)	35.6	?
3. Dubose extract No. 1, solid.....	France	105	Trace (3.75)	35.0	300
4. Dubose extract No. 2, solid.....	France	97	Trace (3.75)	32.5	299
5. Powder of hæmatein.....	Germany	150	7.5 (10)	40.5	316

7. I. Extract for printing	Germany	68	Trace (2.5)	8.8	773

Similarity of procedure is of course necessary for obtaining good results.

In the manufacture of logwood extracts no attempt should be made to convert hæmatoxylin into hæmatein by oxidising agents, such as chlorine; this should be left to the dyer, who can easily bring it about by addition of ammonia and exposure to air. The addition of calcium acetate is to be recommended.—A. G. B.

Report on a Prize Competition for a Practical Method of Preventing the Formation of Oxycellulose in Printing Discharges on Indigo Blue by Means of Chromic Acid.
A. Scheurer. Bull. Soc. Ind. Mulhouse, 1891, 484—486.

The method proposed was to soak the fabric, dyed with indigo, in a solution of sodium silicate of 2° to 4° B. before printing on the discharge. The author tested the method by making comparative trials, and the prepared samples

were printed with the ordinary discharge of alkaline chromate thickened with starch or gum. They were then placed for one minute at 50° C. in a bath composed of 160 grms. of sulphuric acid, 50 grms. of oxalic acid, and 790 grms. of water. After rinsing the samples were then boiled for 30 minutes with 10 grms. of sodium carbonate dissolved in a litre of water. The samples were then tested for strength in a "dynamometer," when it was found that the samples submitted to the sodium silicate treatment were not sensibly stronger than the others. By using a stronger solution of sodium silicate a somewhat more favourable result was obtained, but the discharge was then imperfect, and in fact the alkaline substance seemed to act no better than a thickener of the same viscosity in preventing the tendering action of the acid bath.—G. H. B.

On the Weakening of the Tissue in the Printing of White Discharges on Vat Indigo Blue. A. Scheurer. Bull. Soc. Ind. Mulhouse, 1891, 487—495.

THE first part of this research aims at fixing the limits of the variations to be introduced in the experiments on the various substances which are described in the second part. The method pursued is to print a discharge in a narrow stripe across a strip of cotton sheet 4 cm. broad and dyed with vat indigo blue. The strip is then placed in an acid bath to effect the discharge and washed; it is finally steeped in an alkaline bath to bring out the maximum weakening or tendering, which is measured by the breaking strain exerted in a "dynamometer." Briefly expressed, the author finds that an alkaline bath containing 10 grms. of sodium carbonate in a litre of water has no sensible effect on the tissue during 30 minutes at a boiling temperature, and that variations due to imperfections inherent in the tissue range up to 10 per cent., which is therefore taken as the unavoidable error of experiment. The full period of 30 minutes boiling in the alkaline bath was found to be required to develop the maximum weakening due to the action of the acid bath. It was immaterial to the result whether the strip was tested in the "dynamometer" in a wet or dry condition. Even considerable alteration of the strength of the acid bath did not affect the results beyond 10 per cent., but the effect was sensibly increased when the temperature of the bath exceeded 60° C. The substances whose powers of hindering the weakening of the tissue were to be tested, were added in quantities of 200 grms. each to 1 litre of the acid bath composed of 160 parts of sulphuric acid, 50 of oxalic acid, and 590 parts of water, and the operation of souring and washing of the printed strips were now conducted under the conditions determined by the preliminary experiments. Water, sugar, glucose, formic acid, tartaric acid, acetone, alcohol, and glycerin were experimented with, but the results obtained with the two last only were of interest. Alcohol had been for some years used in this way by Brandt, whilst glycerin was employed by H. Koechlin. The author finds that the protective action of glycerin is proportional to the quantity employed. Of the inorganic substances tried, sodium bisulphite, tin-salt, and arsenious acid stopped the development of the discharge, the sulphates of copper and cobalt increased the weakening effect, and the only favourable results were obtained with manganese chloride and tartar emetic.—G. H. B.

Means of Preventing the Formation of Oxycellulose in the Printing of Discharges on Indigo Blue. Brandt. Bull. Soc. Ind. Mulhouse, 1891, 496—497.

IN order to print a white discharge on cotton tissues dyed with indigo blue, the design is printed with an alkaline chromate solution thickened with gum, and the action of the oxidising substance is developed by a passage through an acid bath containing sulphuric and oxalic acids. But this acid bath is very detrimental to the cotton tissue, as the chromic acid set free gives rise to the formation of oxycellulose, the weakness or tenderness of which is still further increased by the subsequent washing in alkaline or soap solutions. The presence of oxycellulose may be shown by the method proposed by Witz, which consists in dyeing the

tissue with Methylene blue, which does not affect the unaltered cellulose, but dyes those portions converted into oxycellulose to a depth proportional to the degree of conversion. In order to impede the formation of oxycellulose in this kind of printing the author has for four years added 10 per cent. of alcohol to the acid bath with fairly satisfactory results. The weakening was very sensibly decreased, whilst a full discharge was obtained, and the Methylene blue test showed that the conversion of the fibre into oxycellulose was very small. Any kind of debaturated alcohol may be used, as the impurities do not interfere with the results. The author has used glycerin in a similar way with favourable results, but not so good as with alcohol.—G. H. B.

On a Special Process for Preparing "Sulphoricinate." A. Scheurer-Kestner. Bull. Soc. Ind. Mulhouse, 1891, 499—502.

THIS communication begins with the publication of a paper sealed and deposited on 31st July 1889 and opened on 29th April 1891, which states that De Milly was the first who succeeded in effecting saponification industrially by steam, and the author has extended this method to the preparation of Turkey-red oil.

In an additional note the author now gives the results of his examination of the oil, and he finds that the fatty acid obtained in this way is not the normal ricinoleic acid, but an acid of a lower saturation equivalent and giving a more violet shade of red in the alizarin dyeing process. This acid gives a milky solution with ammonia, whilst normal ricinoleic acid gives a clear solution when neutralised with ammonia. Its molecular weight is 480, that of the normal acid being 298. In preparing Turkey-red oil by means of sulphuric acid, there results a mixture of sulphonated and non-sulphonated acids of normal constitution as well as polymerised, the effect of sulphonation tending to produce yellow shades, whilst the polymerisation is favourable to blue shades of alizarin. When a polymerised acid is saponified with soda below 80° C. it remains unaltered and the original acid is reproduced on acidification, but if the saponification be accompanied by prolonged boiling or conducted under pressure at a temperature above 100° C. the normal acid is formed.—G. H. B.

Properties of Cuprammonium. Prud'homme. Bull. Soc. Ind. Mulhouse, 1891, 510—512.

THE author traces an analogy between the action on cellulose of cuprammonium and hydrogen peroxide. In both cases oxycellulose is formed. Cuprammonium appears to have a stronger oxidising power than hydrogen peroxide on indigo blue, which it decolourises quickly. Mercerised cotton is also strongly attacked by it. The blue solution formed by dissolving copper in ammonia in presence of air becomes decolourised when left in contact with excess of copper in a bottle which is quite filled and stoppered, and the copper salt is reduced to the cuprous state. Ammonium nitrite treated with copper in the cold evolves nitric oxide according to the equation—

but in presence of ammonia, nitrogen is given off—

—G. H. B.

Note on a New Chromium Mordant. A. Scheurer. Bull. Soc. Ind. Mulhouse, 1891, 522—524.

THIS mordant is obtained by reducing potassium bichromate with sulphurous acid, and differs from potassium chrome alum by containing less potassium sulphate, and by having a green instead of a violet colour. It is prepared by adding 57 grms. of sulphurous acid to 88 grms. bichromate dissolved in 855 grms. of water. After printing the mordant may be fixed by exposure to ammonia gas. The substance remaining on the fibre is not chromic oxide but a basic

sulphate, which gives a different shade on dyeing. This mordant gives with nitroalizarin a yellowish-rose of great freshness. The same dye gives with a pure chromic oxide mordant a more violet and less brilliant shade.—G. H. B.

The Fusing Point and Crystalline Form of Aluminium Chloride. K. Seubert and W. Pollard. Ber. 1891, 24, 2575—2577.

ALUMINIUM chloride was prepared by heating the approximately pure metal in a stream of dry hydrochloric acid gas and its melting point taken by heating it in a capillary tube in a paraffin bath. The substance boiled up and sublimed at 175°—179° C. and the sublimate fused at 194° C. It crystallised in hexagonal tables about 1 cm. in diameter and 1 mm. thick.—B. B.

The Chlorine Industry. Laboratory Investigations.

A. Reychler. Monit. Scient. 1891, 1249—1256.

I. Regeneration of Manganese Dioxide.—In the Dunlop process for recovering manganese dioxide as carried out at the works of Messrs. Tennant at Glasgow, the operation of calcining the manganese carbonate is effected by circulating the material in small waggons through a special furnace, where it is gradually raised from a low temperature to a higher one (300°—400° C.), the operation lasting about 36 hours. The author finds that this time may be considerably shortened by simply heating the carbonate briskly upon an iron plate, taking care not to let the temperature rise to that of incipient redness. In this way he obtains in less than one hour a black pulverulent product containing 60 to 75 per cent. of available peroxide of manganese, which would be very suitable for industrial use if it did not also still contain too much carbonic acid. This product can be made richer in peroxide by moistening it with water to which nitric acid has been added equal to one-third or one-fourth of the remaining manganous oxide. The substance is then dried, and afterwards calcined for a couple of hours at 125°—260° C., when nitrous vapours equivalent to 9—10 per cent. of the nitric acid added are given off, and a product free from carbonic acid (but retaining sometimes a trace of nitric acid) is recovered, which contains from 91.5 to 93.5 per cent. of manganese dioxide. This treatment resembles the Kuhlmann process, but differs from it in only converting into nitrate the manganous oxide left after the first calcination, instead of converting the whole of the manganese into nitrate. If this modification of the Kuhlmann process had originally been worked conjointly with the Dunlop process, it is probable enough that it might have become an industrial process. The development of the chlorine industry, however, is now following another course.

II. The Weldon Process with Magnesia (modified).—

This process may be considered in two phases:—1st. The manganite of magnesia ($MnMgO_3$) is agitated with concentrated hydrochloric acid, giving a solution of manganous chloride and magnesium chloride, and liberating chlorine equal to about one-fourth of the chlorine in the acid used. 2nd. The solution of the chlorides is evaporated and the residue calcined in a reverberatory furnace with two compartments, similar to a salt-cake furnace. In the "pan" the material continues to lose water, but yields also hydrochloric acid and chlorine, and in the "furnace" it yields chiefly chlorine and becomes oxidised by the air, re-forming the manganite. The calcination must be conducted with the greatest care, on account of the easy fusibility of the mixed chlorides. The chlorine obtained is very much diluted and difficult to use.

(a.) *The Fusibility of the Chlorides* may be overcome by adding to them a certain amount of magnesium sulphate.

If equivalent quantities of magnesium chloride, manganous chloride, and magnesium sulphate, are melted together in their water of crystallisation and the mixture heated in a sand-bath, a solid residue, apparently dry, but still retaining, however, a certain quantity of water, is obtained. This residue may be calcined quickly at a red heat without fusing, and leaves a black mass which is tolerably consistent, very porous, and only retains a trace of chlorine. The sulphate of magnesium can be extracted from this mass by washing with water, and a black manganite remains which is easily attacked by acids and which contains about 47 per cent. of manganese dioxide. The formula $Mn_2Mg_3O_8$ corresponds to 47.67 per cent. of dioxide. This compound may be looked upon as a mixture of two oxides of the magnetic type in which magnesia replaces a part of the manganese $MnMg_2O_4 + Mn_2MgO_4$. The product of the calcination has the formula—

Such a mixture ought, in fact, to disengage chlorine from hydrochloric acid equal to one-fourth the chlorine contained in the acid used. The quantity of magnesium sulphate may be increased or diminished without affecting the composition of the manganite to any great extent. Other mixtures have been tried but none was so satisfactory as the Weldon mud mixed with magnesium sulphate.

(b.) *The Hydrochloric Acid and Chlorine liberated on Calcination.*—The author heated the dried residue of manganese and magnesium chlorides mixed with magnesium sulphate in a porcelain tube at a dull red heat and in a current of air. The temperature and the humidity of the air have an influence upon the nature of the gases evolved. The evolved gases were analysed by absorbing them in an alkaline arsenious acid solution of known strength; in one portion of the solution the unoxidised arsenious acid was determined and in another portion the amount of hydrochloric acid produced was estimated. The following are some of the results obtained: 1. Equivalent quantities of the three substances were used. The total weight of the dried residue was 13 grms. The air passed through the tube during calcination was saturated with moisture. 25.75 per cent. of the chlorine was liberated. 2. Twice the above amount of magnesium sulphate was used. The humidity of the air used was that of the atmosphere at the time of the experiment. 10.15 per cent. of the chlorine was evolved as HCl during the desiccation of the material, 67.65 per cent. as HCl during the calcination, and 22.2 per cent. as free chlorine. 3. The air before coming in contact with the substance was passed through a drying apparatus and then over a layer of fragments of sandstone heated to redness. Under these conditions 50 per cent. of the chlorine was evolved in the free state. According to Lunge, Weldon obtained a similar result.

The utilisation of this diluted chlorine is a difficult problem to solve. Weldon could scarcely make any use of it except for making chlorates or a solution of chloride of lime.

(c.) *Action of Hydrochloric Acid upon the Product of Calcination.*—When the residue, $Mn_2Mg_3O_8 + MgSO_4$, is treated with water or with hydrochloric acid, it becomes

heated and forms nodules of which the interior parts are withdrawn from the action of the acid. In practice, it would therefore be necessary to begin by grinding the calcined residue with a moderate amount of water, to let it settle, and then use the mud for making chlorine. In his laboratory experiments the author extracted the magnesium sulphate with water and used the insoluble residue for generating chlorine. It yielded chlorine equal to the theoretical amount, according to the equation—

A quarter of the chlorine of the acid is evolved as free chlorine. Weldon's manganite, to which he gave the formula, MnMgO_3 , also yields one-fourth of the chlorine in the hydrochloric acid used to dissolve it, a fact, however, which is not in accordance with that formula.

One of the difficulties, therefore, of the Weldon magnesia process, the fusibility of the mixed chlorides, has been overcome. The other drawbacks of the process, cost of evaporation and difficulty of utilising the dilute chlorine, still exist.

III. DE WILDE AND REYCHLER'S PROCESS.

(a.) *With Sulphate and Chloride of Magnesium.*—When a current of hydrochloric acid gas is passed over a calcined mixture of the sulphate and oxide of magnesium contained in a porcelain tube heated to a temperature rather lower than that of incipient redness, the greater part of the acid is absorbed and a certain amount of water is formed. If the product thus obtained be now heated to dull redness in a current of air, it evolves chlorine mixed with a certain amount of aqueous vapour and hydrochloric acid, and the original substance is regenerated ready to be again acted on with hydrochloric acid gas. The discovery of this fact is due to Prof. De Wilde. The author has investigated the reactions quantitatively in his laboratory. He finds that after the mixture of sulphate and oxide has ceased to absorb hydrochloric acid gas, it contains Cl—18·18 per cent., SO_4 —51·90 per cent., Mg—23·72 per cent., from which the following composition may be deduced:—

	Per Cent.
MgCl_2	24·33
MgSO_4	64·94
Mg(OH)_2	10·02
MgO	0·71

or—

	Per Cent.
MgCl(OH)	28·43
Mg_2OCl_2	2·40
MgCl_2	6·23
MgSO_4	64·94

The chlorination is therefore incomplete and is accompanied by an hydratine. The latter fact was also been noted by Mond and Eschellmann.

The reoxidation of the product requires an incipient red heat, or even a dull red heat. The air was dried before passing it over the substance, and was also heated to the temperature of the experiment by passing it first over a layer of heated fragments of sandstone. Allowing 1 litre of air to pass in 15 minutes, the gases evolved contained—

At the end of 20 minutes, 14·5 vols. per cent. of Cl and 38·5 vols. per cent. of HCl .

At the end of 56 minutes, 16·3 vols. per cent. of Cl and 40·44 vols. per cent. of HCl .

At the end of 92 minutes, 12·1 vols. per cent. of Cl and 0 vols. per cent. of HCl .

On continuing the experiment, 8, 6·5, 10·5, 10, and 9 vols. of chlorine per cent. were evolved according to the degree of heat employed. Even at a bright red heat the chlorine evolved only amounted to 12 to 13 vols. per cent. The drawbacks to the process are that the chlorine evolved is not concentrated, and that at the beginning of oxidation it is mixed with a large quantity of hydrochloric acid.

(b.) *With Magnesium Chloride, Manganous Chloride, and Magnesium Sulphate.*—Recognising the advantages of de Wilde's method, the author conceived the idea of applying the principle to other active substances, especially to the manganite of magnesium, and in this way as it were elaborating a *dry Weldon process*. The calcined mass employed was that having as already shown the composition $3 \text{MgSO}_4 + \text{Mn}_3\text{Mg}_3\text{O}_8$. This substance was treated in a porcelain tube with gaseous hydrochloric acid made from ammonium chloride and sulphuric acid, and raised to the temperature of the experiment by passing over heated fragments of sandstone. The reaction goes on best at a temperature below incipient redness, about 400° — 450° . At 300° very little chlorine is evolved, whilst at dull redness a considerable quantity of oxygen is evolved. In an experiment lasting five hours, during which the chlorine and hydrochloric acid which had been evolved during each hour were estimated at the end of each hour, the following results were obtained:—

	46·0	51·8	48·4	46·2	24·4	Mean
Vols. per cent. of chlorine.	46·0	51·8	48·4	46·2	24·4	43·4
Vols. per cent. of acid.....	33·3	35·2	51·6	51·4	75·6	49·4

In the tests made at the end of the first hour air was still present, whilst at the end of the second hour the gases evolved contained oxygen. Another experiment, lasting six hours, gave a mean result of 50·2 vols. per cent. of chlorine and 47·7 vols. per cent. of hydrochloric acid.

The chlorinated material obtained is still somewhat dark coloured, but shows numerous white particles. When powdered it has a light grey colour. It was found to contain from 31 to 36·5 per cent. of chlorine. It is probable that the manganese is converted into manganous chloride, and the magnesium chiefly into oxychloride slightly hydrated. The hydrochloric acid utilised may be calculated from the formula—

One volume of chlorine evolved corresponds to 8 vols. of HCl used. In the first experiment, therefore, the volume of acid utilised was $43·4 \times 8 = 347·2$. The total volume employed was $347·2 + 49·4 = 396·6$, which shows a utilisation of 87 to 88 per cent. of the acid employed. The percentage of acid utilised in the second experiment was 89 to 90 per cent. Making allowance for the fact that the magnesia is only about one-half chlorinated and forms oxychloride instead of chloride, one volume of chlorine evolved is equivalent to 6·5 volumes of acid, which gives therefore a utilisation of the hydrochloric for these two experiments, equal to 85 per cent. and 87 per cent. respectively.

Action of Air upon the Chlorinated Mixture.—On passing a current of dry air at constant speed over the chlorinated mixture heated to incipient redness (525°) the evolved gases contain from 16 to 20 volumes per cent. of chlorine. At a dull red heat or at a bright red, the percentage of chlorine may even rise to 25 per cent. Using 85 grms. of the substance, and a current of air passing at the rate of 1 litre in 8 to 10 minutes, from 5 to 6 hours suffice to expel about two-thirds of the chlorine present. Towards the end the evolved gases become weaker and contain from 12 to 14 vols. per cent. of chlorine.

Treatment by a Mixture of Air and Gaseous Hydrochloric Acid.—The author has made numerous experiments to investigate this modification. As a general result, he finds that the concentration of the chlorine evolved is not much less than that obtained by the treatment of the chlorinated substance with air alone. But, on the other hand, there is not so great an economy of the hydrochloric acid by the mixed treatment, as it is far from reaching the utilisation of from 80 to 90 per cent. found by the alternating treatment (in an example cited the utilisation of the hydrochloric acid by the mixed air and acid treatment amounted to 50 per cent.).

The reactions that take place in the mixed air and acid process may be expressed by the two following equations:—

I.

II.

For descriptions of De Wilde and Reyche's process see also this Journal, 1890, 510 and 1128.—H. S. P.

The Action of Sulphurous Acid on Flowers of Sulphur.
A. Colefax. Proc. Chem. Soc. 1891—1892, 180.

DEBUS's statement that sulphurous acid has practically no action on sulphur is not confirmed. Sulphurous acid acts on flowers of sulphur at the ordinary temperature of the air, and produces thiosulphuric acid and a polythionic acid, probably trithionic acid. No pentathionic acid was found. According to Flückiger (Jahresbericht, 1863, 149), sulphurous acid gave, by its action on flowers of sulphur, thiosulphuric acid. The presence of a polythionic acid is proved by a comparison of the iodine titrations and the acidity titrations before and after the addition of iodine requisite for the iodine titration. It is thus shown that there is present a considerable quantity of an acid having no iodine titration, and which is not merely oxidised sulphurous acid. (Qualitative tests point to the presence of thiosulphuric acid, or trithionic acid, or a mixture of the two. Not even in the dark is sulphurous acid without action on sulphur. A higher temperature (say 80°—90° C.) favours the action of sulphurous acid on sulphur; water has no action on flowers of sulphur, either at ordinary temperatures or at this higher temperature.

PATENTS.

Improvements in the Manufacture of Barium Chloride and Strontium Chloride. M. N. D'Andria, Manchester. Eng. Pat. 1168, January 22, 1891. 4d.

The sulphides of barium or strontium, obtained by the reduction of the corresponding sulphates, are treated with a neutral solution of iron protochloride (a by-product from galvanising); the solution of alkaline earthy chlorides is filtered "from the remaining sulphide of iron formed" and is evaporated to crystallisation. In an alternate way of working the iron protochloride is furnished along with the sulphate and coal, and the chlorides dissolved out at once from the reduced mass.—H. A.

Process for Bleaching and Purifying Aluminium Sulphate.
O. Imray, London. From "La Société Anonyme des Anciennes Salines Domaniales de l'Est," Paris, France. Eng. Pat. 1261, January 23, 1891. 4d.

A product free from iron can be obtained by the addition of a sulphite, bisulphite, or hyposulphite (preferably of soda), or barium dioxide and dilute acid, or oxygenated water, to a slightly acid and nearly boiling solution of aluminium sulphate.—H. A.

Improvements in Apparatus for Concentrating Acids. W. C. Herrens, Hanau, Germany. Eng. Pat. 2499, February 11, 1891. 4d.

The platinum apparatus hitherto in use for concentrating sulphuric acid labours under the disadvantage of being attacked by concentrated acids. A coating of gold renders the vessel more durable, but up to the present no really satisfactory coating has been applied, and it has also been found impractical to repair such coated apparatus. The

invention consists in the production of such coating by heating the sheet platinum to a temperature higher than the melting point of gold, and then pouring the molten gold over it, in any convenient form of mould; the double sheet is then rolled out to any desired thickness. Vessels made from these double-sheets also serve as substitutes for gold pans.—H. A.

Improvements in the Manufacture of Caustic Alkali, Carbonates of the Alkaline Metals and Muric Acid, and of Bricks, Cakes, or Blocks for use therein, and Apparatus therefor. H. H. Lake, London. From The Kayser Patent Company, Jersey, U.S.A. Eng. Pat. 10,202, June 16, 1891. 1s. 1d.

The improvements refer to the decomposition of a mixture of clay and salt, for the production of the above enumerated substances. A tough mixture of clay (containing a proportion of 1½ lb. of silica to 1 lb. of alumina, to render the mass as refractory as possible) and of dense salt is moulded into cakes of cylindrical shape, provided with a central channel. The cakes are dried and hardened by gradual heating to 220°—250° F. in a special furnace, through which a current of hot air is passed. A contrivance is described for charging the furnaces, and keeping the cakes from breaking or pulverising, so as to maintain free access of the gases to all parts of the charge. There are four furnaces or converters, cylindrical on top and sufficiently conical on the bottom to allow the whole finished charge to roll out. Cooled generator-gas, or water-gas, or natural gas is forced in the top part of any of the converters, the inlet being above the charge and in tangential direction to the periphery of the converter, whereby a thorough and uniform heating of the charge is said to take place. The gases sink down and can be led by means of a vertical shaft from the bottom of a converter to the gas inlet of the next converter, or, by means of a downward extension of the shaft, to an underground passage, to be further treated for the recovery of hydrochloric acid. All connexions are provided with dampers. Air, steam, and gas are introduced together into any of the converters. A ring made of fire-bricks and provided with radial openings separates the gas passage on the bottom and its outlet from the interior of the converter. Below this ring is the discharge opening which is closed by means of a plate provided with tapholes and with a central opening.

In working the process the supply of gas, air, and steam, are so regulated as to obtain an oxidising flame. The charge is finished in about four days, and the operation is so conducted that the united gas mixture raises first the contents of a particular converter to white heat, the products of combustion, containing hydrochloric acid, being drawn off through the underground passage; with an increase of temperature some of the salt fuses and has to be drawn off through the tapholes on the bottom. Meanwhile the next converter has been heated independently, and when sufficiently hot to prevent the choking up of the passages with sublimed salt, the combustion gases from the first converter are admitted along with generator gas, and the escaping hydrochloric acid is again conducted into the underground passage. While this is proceeded with, the third and fourth converters are also heated independently, the former having been recently charged and the latter just finishing off.

The drawn charge consists of an acid, "sodium-silico-aluminate," which may be converted into the soluble basic salt by fusing with alkali (soda-ash); if the product so obtained contain only 40—42 per cent. soda, the action on the lining of the furnace will not be so destructive. The basic salt is next broken up and "leached systematically until the lye shows about one degree B." (1.5° Tw.). "The insoluble remainder is hydrous sodium-silico-aluminate with from 17—20 per cent. of sodium oxide." This is ground up, suspended in water, and boiled with milk of lime. The clear alkaline solution of 4°—5° B. (6°—7.5° Tw.) is utilised for leaching a fresh quantity of the basic salt. The residue of "hydrous calcium silico-aluminate" is washed in a filter-press, and produces on exposure to the air calcium carbonate, silica, and alumina,

a mixture which is "an entirely new article and capable of many practical applications" and "is furthermore distinguished by containing a very large quantity of chemically bound water when air dried (say 30 per cent.)."

An alternate way of working consists in omitting the leaching operation, and treating the basic salt direct with milk of lime or carbonic acid, for the production of caustic soda or sodium carbonate.

In a third alternate method the acid salt need not be converted into basic salt, but its mixture with calcium oxide or calcium carbonate is heated to a high temperature whereby sodium aluminate and insoluble "calcium-silico-aluminate" are obtained. The solution of the former may be decomposed with carbonic acid for the production of sodium carbonate, or treated with milk of lime for the preparation of caustic alkali, the secondary reaction being the precipitation of pure alumina (as much as 16—18 per cent.) in the first place, and of insoluble calcium aluminate in the second instance. The residual calcium-silico-aluminate may be calcined and utilised as a hydraulic lime.

The combustion gases passing from the converters to the underground flues contain hydrochloric acid and some volatilised salt. The gases are exhausted by means of a fan, and passed through a tower filled with coke for separating the salt, and from thence into condensers for the recovery of hydrochloric acid.

Fifteen claims are made and three sheets of drawings accompany the specification.—H. A.

A Process for the Production of Caustic Alkali, Carbonate of Alkaline Metals, and Useful Bye-Products. F. Eichstädt, Göteborg, Sweden. Eng. Pat. 15,136, September 7, 1891. 6.

"THE invention for the production of caustic alkali depends upon the interchange effected between sulphates of the alkalis and hydrates of the alkaline earths, barium and strontium, to form hydrates of the alkalis, and sulphates of the alkaline earths." Strontium hydrate is preferably employed for this purpose. "The strontium hydrate is preferably produced by the novel reaction produced by the sulphides of strontium and sodium in solution in water." (Compare C. F. Claus, Eng. Pat. 1096 of 1883; this Journal, 1883, 476), for which purpose the inventor proposes to roast equivalent quantities of strontium sulphate and sodium sulphate with a quarter of the weight of the mixture of coal and dissolving the melted mass in boiling water. The reactions can be expressed by the equations—

The strontium hydrate crystallises out on cooling, and may be purified by recrystallising; the mother-liquor from the strontium hydrate crystals, consisting chiefly of sodium sulphhydrate, may be utilised in various ways. Thus addition of sulphuric acid produces sodium sulphate, with evolution of sulphuretted hydrogen, which may be treated for the production of free sulphur or sulphuric acid. Or treatment with an insufficient quantity of sulphurous acid produces a certain amount of hyposulphite in the solution and a subsequent addition of sulphuric acid causes formation of sodium sulphate and of precipitated sulphur, but no evolution of sulphuretted hydrogen. Or the hydrosulphide of sodium may be oxidised atmospheric air, to produce hyposulphite, which is then treated with sulphuric acid.

The caustic soda solution, resulting from the treatment of the redissolved strontium hydrate with sodium sulphate, may be carbonated for the production of alkaline carbonate.

—H. A.

Improvements relating to Carbonic Acid Baths and Tablets for use therein. E. Sandow, Hamburg, Germany. Eng. Pat. 16,422, September 28, 1891. 4d.

THE bath consists of a solution of sodium bicarbonate, from which it is proposed to liberate carbonic acid, not with hydrochloric acid as heretofore, but with sodium bisulphate, cast in tablets of suitable shape, which can be

moved about in the bath. The gas may thus be generated near any part of the body. A "steel bath" may be produced by dissolving a melted mixture of sodium bisulphate and ferrous sulphate.—H. A.

Improvements in the Manufacture of Alumina. W. P. Thompson, Liverpool. From J. A. Bradburn and J. D. Pennock, Syracuse, U.S.A. Eng. Pat. 17,933, October 20, 1891. 4d.

THE object of this invention is the manufacture of alumina from bauxite, preferably from that variety of the mineral which contains the iron in the ferric state and is contaminated with but little or no organic matter. The difficulties connected with "the art of obtaining alumina from ferrous bauxite" are overcome by mixing the ground mineral with a solution of bleaching powder and passing carbonic acid through the mass; the chlorine thus liberated oxidises the iron and organic matter. The bauxite is then digested with a caustic soda solution containing, say, 150 grms. of Na₂O per litre, which extracts the bulk of the alumina. The solution is filtered off. Should the residue contain a paying quantity of alumina, it is heated with $1\frac{1}{2}$ to 1 $\frac{1}{4}$ parts of sodium carbonate, and the resulting mass lixiviated with the sodium aluminate solution previously obtained. The resulting tank-liquor has a turbid appearance, which is due to iron in suspension; it may be clarified by the addition of milk of lime, the gelatinous precipitate of hydrated alumina thus produced carrying down the iron with it.

The filtered and heated liquor is now precipitated with sodium bicarbonate, and after washing the alumina "with a reasonable amount of water," it is heated with a solution of ammonium chloride, which converts the soda into common salt. This is easily washed out, and the pure alumina is then filtered, dried, and calcined.—H. A.

An Improved Process for Manufacturing Nitrate of Ammonia or Chloride of Ammonia, simultaneously obtaining either Precipitated Phosphate of Lime or an Enriched Phosphate of Lime. L. Brummer, Wetzlar, Germany, and A. Zanner, Laeken, Belgium. Eng. Pat. 18,324, October 24, 1891. 4d.

THE poorer varieties of phosphates may be enriched by treating the phosphatic rock with a sufficient quantity of nitric acid to dissolve the impurities alone, which consist chiefly of calcium carbonate. A bi-calcium phosphate is obtained by increasing the quantity of nitric acid used, in order to dissolve the phosphate as well, and precipitating it with ammonia, gas-liquor, or milk of lime. The resulting solution contains in either case calcium nitrate, and in the latter case ammonium nitrate as well. Three alternate methods are given for converting this calcium nitrate into ammonium nitrate, viz.:—(1) Treatment with ammonium carbonate, or carbonic acid in a solution of ammonia, the by-product being calcium carbonate. (2) Treatment with ammonium sulphate, with simultaneous formation of calcium sulphate. (3) Small quantities of calcium nitrate may be precipitated with phosphoric acid, in presence of ammonia.

Instead of the nitric acid, hydrochloric acid may be employed for the production of ammonium chloride; or a mixture of nitric acid and sulphuric acid may be used with advantage.—H. A.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Manufacture of Glass Pipes of Large Diameter. L. Appert. Bull. Soc. d'Encouragement l'Industrie Nationale, 1891, 6, 114—121.

GLASS tubes of large size are costly when produced by the ordinary method of blowing, owing to the fact that none but the very best workmen can produce them. The ordinary method of coating only admits of the production of short tubes of considerable thickness. In this memoir improved machinery for casting or moulding such tubes is figured and described. The molten glass in the required state of fluidity is run into a strong iron mould, which is then closed, and the workman regulates the rapidity of passage of the spindle or core according to the dimensions of the tube. The mould is then opened and the tube taken out for annealing. With tubes of 100 mm. diameter, 15 can be made in an hour. Two metres is a usual length, which would give 30 metres an hour, but that 20 per cent. must be deducted for failures, giving an effective output of 24 metres an hour, or about 500 metres per diem.

Four men and a boy are employed in the work. The power (steam or compressed air) required for driving the cone or spindle is very slight. The facility of working is greater with the larger size of tubes.

The method of connecting the tubes depends on the use to which they are put, metallic joints being used for tubes designed for the passage of water at high pressure.—V. C.

A Method of Hardening Plaster Casts. M. Denstedt, Ber. 1891, 24, 2557—2558.

See under IX., next column.

PATENTS.

Improvements in Forming Under-cut Projections and Recesses in Tiles and other Articles of Pottery, and in Apparatus therefor. H. L. Doulton and S. H. Leech, Lambeth. Eng. Pat. 943, January 19, 1891. 8d.

IN this process under-cut projections or recesses are formed by pressing against the clay pieces or perforated sheets of india-rubber or other elastic material, one face of which is held, whilst the face next the clay spreads out laterally by the pressure. On one or more of the faces of the mould are fixed projections of india-rubber, furnished with projections if it is desired to make under-cut holes, or with holes if it is desired to make under-cut projections. When pressure is applied, the india-rubber spreads laterally on its face next the clay, whilst the surface in contact with the mould remains fixed. When the pressure is relieved the india-rubber resumes its former shape, which facilitates delivery.—V. C.

Improvements in Baking Ceramic Pastes and Pottery. C. G. Losada, Seville, Spain. Eng. Pat. 14,381, August 25, 1891. 11d.

THE invention consists in an improved continuous oven for baking ware, and in special interior fittings for the same. The advantages are as follows: The goods are only introduced into the oven when the latter is in proper condition for melting the glaze. Economy of fuel is said to be effected. Saggers and stilts are not required owing to the arrangement of trays of refractory material moveable on rollers. The process is capable of being regulated accurately, as the chambers are open at the ends and the progress of the operations can be watched.—V. C.

Improvements in the Liquid Material or "Slip" used in the Manufacture of Porcelain, Stoneware, and the like. E. Edwards, London. From K. Goetz, Karlsbad, Germany. Eng. Pat. 18,189, October 22, 1891. 4d.

THE process consists in preparing the liquid or "slip" by mixing the material used with an aqueous solution of carbonate of soda, bicarbonate of soda, calcined soda or soda ash, instead of mixing the material with water. One of concentrated solution to 1,500 of the material is sufficient. The following advantages are claimed over "slip" made by the ordinary process, viz., that the fluid pours better, articles being made in one mould which formerly required two or three. Articles can be made in moulds which ordinarily have to be turned or shaped separately. Increased rapidity of production. The articles are of more uniform quality and stronger. The mould can be used more frequently without drying. The shrinkage is considerably reduced, the temperature required is lower, and the grinding operations take less time. A further point connected with the same invention is the mixing of a small quantity of einnabar with the materials of the "slip" to prevent the swellings and the grey colour sometimes produced upon porcelain, especially at the edges, during burning.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

A Method of Hardening Plaster Casts. M. Pennstedt. Ber. 1891, 24, 2557—2558.

THE method consists in immersing the plaster cast to be hardened in a solution of silicic acid so that it becomes saturated, and afterwards permitting it to dry so that the silica passes into the insoluble state and remains diffused throughout the mass. The article under treatment is then transferred to a saturated solution of barium hydrate kept at a temperature of 60°—70° C. for a short time, then removed and dried in a moderately warm place. Casts may also be hardened by the admixture with the plaster before casting of metallic hydrates (e.g. those of aluminium and zinc) and subsequent treatment with silicic acid, with which they unite to form silicates.

Coloured casts may be produced by treating the articles to be coloured with a weak solution of some suitable sulphate, such as sulphate of copper, before immersion in the hot solution of barium hydrate.—B. B.

PATENTS.

Improvements in and Apparatus for the Manufacture of Cement. W. R. Taylor, Rochester. Eng. Pat. 1115, January 21, 1891. 8d.

THE first improvement claimed by the patentee consists in mixing the raw materials (e.g. clay and chalk) for making cement by blowing them together, either powdered or suspended in water or some liquid hydrocarbon by means of a jet of air, steam, or other fluid. The materials thus prepared may be moulded into perforated bricks and burnt in a revolving kiln such as is described in Eng. Pat. 5719 of 1890 (this Journal, 1891, 466). The flue of the kiln is water-jacketed, the water thus heated being used for mixing with the raw materials or for boiler purposes. Another improvement consists in exposing the raw material in the form of bricks to the flue gases by means of a travelling band or other form of conveyor. A claim is made for drawing off carbon dioxide from the kiln flue and utilising it in the ordinary way. The waste heat of the kilns may also be utilised by introducing water pipes or coils at the top of the kiln or the flue in such a manner as not to impair the draught, the water being used in the same way as that circulating through the annular space between the flue proper and its outer covering.—B. B.

Improvements in the Manufacture of Artificial Roman Cement. C. von Forell, Brunswick, Germany. Eng. Pat. 1750, January 30, 1891. 4d.

THE patentee states that seeing that nearly all Roman cements contain more or less uncombined lime owing to the comparatively low temperature at which they are burnt, such cements may be mixed with raw materials rich in alumina, such as silicate of alumina, in such proportion that the ratio of the lime to the hydraulic factors is about 1.7 : 1. The aluminous material must be finely powdered. It is said that a material is thus obtained of much higher quality than ordinary Roman cement.—B. B.

X.—METALLURGY.

Reduction of Oxygen Compounds by Magnesium. C. Winkler. Ber. 1891, 24, 1966—1984.

THE results of Brauner's recent determinations and the author's present results have led to the relinquishment by the author of the view entertained by him as to the relegation of lanthanum to the 4th periodic group. His experiments on the behaviour of oxygen compounds when mixed with magnesium and heated in an atmosphere of hydrogen, have now been extended to the metals of the 1st, 2nd, and 3rd periodic groups.

The members of the 1st group do not yield hydrides under the conditions of the author's experiments, because the heat developed is sufficient to decompose any such compounds; the hydrides Na_2H_2 , K_2H_2 , for example, decompose at a moderately high temperature. However, under experiment, lithium and sodium hydroxides or carbonates underwent reduction with dangerous violence, and potassium and rubidium compounds developed great heat whilst with cesium hydroxide the action was so violent that ignition of the hydrogen ensued, and a sintered mass of cesium and magnesium oxides was obtained.

In Group II. the oxides of zinc, cadmium, and mercury, on account of the violence of their reduction, were not further considered, but the alkaline earthy oxides proved of great interest; as a rule, when the mixture of any of these oxides with the proper proportion of magnesium was heated in a current of hydrogen, at first an expansion took place, but as the heat was continued and increased, absorption of the gas ensued at a rate varying with the oxide under investigation. In some cases the continuance of high temperatures for some hours necessitated the employment of iron tubes for the experiments in this group. The products were always allowed to cool in an atmosphere of hydrogen, and were analysed as soon as possible after preparation.

Beryllium.—When a mixture of 25 parts by weight (1 mol.) of beryllium oxide and 24 parts by weight (1 atom) of magnesium powder was treated in the manner described, at a red heat, hydrogen absorption commenced but slowly, and progressed tardily but continuously, reaching a maximum in half an hour, then falling slowly from 10 to 4 bubbles a minute, at which it remained at the termination of the experiment at the end of four hours. The light brownish-grey product had not sintered. In contact with the air it emitted an unpleasant odour, and evolved hydrogen very sparingly with cold water, more decidedly with boiling water, but violently with dilute hydrochloric acid, in which case a considerable quantity of unattached beryllium oxide remained undissolved. The product could be heated in a porcelain crucible to incipient redness without alteration, but at higher temperatures it glowed and emitted a hydrogen flame; this flame, as well as the formation of water, were especially pronounced when the heating took place in a current of oxygen. The following was the composition of this product:—

BeH	BeO	MgO	Mg	Total.
3.33	45.10	45.05	6.24	100.00

showing that 14.96 of the beryllium employed had undergone conversion into hydride.

Magnesium.—A mixture of magnesium oxide and magnesium powder in similar proportions and under similar treatment behaved very much in the same way as the beryllium mixture. The product was almost white, had not sintered, and had the composition—

MgH	MgO	Mg	Total.
3.51	82.06	14.40	100.00

showing that only 6.42 per cent. of the original magnesium oxide had been reduced. It had an unpleasant odour, and even with cold water evolved hydrogen slowly with effervescence. Heated in the air, it first emitted a hydrogen flame, then glowed with dazzling brightness, and finally exhibited the luminous flame of burning magnesium. In oxygen, the hydrogen flame and the formation of water were better seen.

Calcium.—The behaviour of the mixture of calcium oxide and magnesium under the conditions of these experiments was not so sluggish as in the preceding cases; the absorption commenced tardily, but reached the rate of 120 bubbles a minute in half an hour, and was practically complete at the end of four hours. The slightly sintered, light grey product had the composition—

CaH	CaO	MgO	Mg	Total.
33.14	28.31	37.66	0.89	100.00

Hence 61.52 per cent. of the original calcium oxide had become converted into hydride. On exposure to the air it swelled up and fell to powder, and hydrogen was evolved from it most vigorously, either by the action of water or dilute hydrochloric acid. Heated in air it burnt faintly, and became surrounded with slightly luminous flame, whilst in oxygen it inflamed with slight explosion and burnt with great brilliancy, the hydrogen flame being distinct, and the formation of water abundant.

Strontium.—Strontium oxide was prepared from the pure carbonate, mixed with the suitable proportion of magnesium powder, and heated in hydrogen, when, after the preliminary expansion, absorption set in rapidly at an incipient red heat, but soon commenced to fall off, and terminated altogether within two hours. The slightly sintered, greyish-brown product was composed of—

SrH	SrO	MgO	Mg	Total.
66.23	4.17	28.93	0.77	100.00

indicating a conversion of 94.91 per cent. of the original strontium employed into hydride. It was very readily oxidised; in the air it at once turned grey, became hot, swelled up, and, with the evolution of hydrogen, formed strontium hydroxide. With water, it gave off hydrogen with effervescence. Heated in air or oxygen, it inflamed in the latter case with a slight report, showing a hydrogen flame at first, and then burning quietly itself. Impure strontium oxide, containing carbonate, was not only more troublesome to deal with, but also gave a less satisfactory result.

Barium.—With this metal also, some difficulty was experienced in getting a pure oxide and ultimately baryta of the following composition:—

BaO	Ba(HO) ₂	BaCO ₃	Al ₂ O ₃	SiO ₂	Total.
71.26	18.13	7.34	1.87	1.10	100.00

was employed, and in the experiments the precaution of heating up in a moderately rapid current of hydrogen, had to be taken to obviate disaster from the realisation of the reaction $\text{Ba(HO)}_2 + \text{Mg} = \text{BaO} + \text{MgO} + \text{H}_2$. This danger over, the end of the tube was closed, and at a red heat absorption set in with vigour and was complete in two hours. The product had the following composition:—

BaH	BaO	MgO	Al ₂ O ₃	SiO ₂	O (excess)	Total.
70.33	4.27	29.99	1.63	0.97	1.73	99.95 (100 in the paper.)

and resembled the strontium compound in character and reactions, the latter being somewhat more energetic in this case.

The author alludes to the probable existence of these particular hydrides in the glowing atmospheres of the sun and certain fixed stars.

Group III.—In this group neither boric anhydride nor alumina were reduced by this method of treatment. With yttrium oxide, however, absorption was moderate but distinct; it soon diminished, and stopped in an hour. The light brownish-grey product evolved hydrogen very slightly with boiling water, not at all with cold water, violently with hydrochloric acid, and when heated in air or oxygen burnt, giving a small flame feebly luminous in the latter case. It had the composition:—

Y ₂ H ₃	Y ₂ O ₃	MgO	Mg	Total.
12.88	72.56	10.15	4.41	100.00

Pointing to the conversion of 18.44 per cent. of the yttrium employed into hydride, this conversion is not as complete as in the case of lanthanum, but nevertheless shows that the latter is not the only member of periodic Group III. capable, when in the nascent state, of combination with hydrogen.—D. A. L.

On the Colloidal Sulphides of Gold. E. A. Schneider. Ber. 1891, 24, 2241—2247.

This is a paper on the preparation and properties of the colloidal sulphides of gold with reference to the occurrence of gold in nature.

The formation of "colloid solutions" by washing precipitates which previously had been treated with another compound in quantity insufficient to effect complete solution has already been observed. Wright (J. Chem. Soc. 1883, 43, 163), has stated that freshly precipitated sulphide of iron passes over into the colloid state when treated with potassium cyanide solution, so that a portion of it passes into solution. On washing the residual sulphide of iron with water, a portion of it passes through the filter and forms a colloid solution.

The present author has confirmed that experimentally. Indeed some years before Wright's observation the author had remarked that on digesting ferric hydrate with aluminium chloride solution, the former passes into solution, and if an excess of ferric hydrate be employed and the

washing continued till all salts are removed, a colloid solution is formed which is very similar in properties to the ordinary colloid ferric hydrate solution.

Gold chloride solution was incompletely precipitated with sulphuretted hydrogen, and the resulting liquid placed upon a dialyser; after the course of some hours the gold chloride solution had diffused through, while on the dialyser, however, instead of the expected auro-aure-sulphide, finely divided gold was found. Without doubt, the gold chloride had acted upon the auro-aure-sulphide according to the following equation:—

In point of fact, a mixture of colloid auro-aure-sulphide with gold chloride does give rise to a separation of metallic gold.

The following results were arrived at:—

1. That the separation of gold in nature is due to the action of sulphuretted hydrogen on solution of gold chloride; since the pyrites, which always accompanies gold, owes its origin to the action of sulphuretted hydrogen solution on ferric oxide compounds, at temperatures below 100°.

2. That the separation of gold is possible at a very slight depth, and where the temperature does not exceed 100°, since it is shown in the above paper that gold chloride separates gold from auro-aure sulphide (Au_2S_3) at temperatures much below 100°.

3. That the formation of pyrites has taken place nearer the surface than the separation of the gold; or that in any case the formation of pyrites and separation of gold were not simultaneous. For the mineral acids formed during the separation of gold by the action of gold chloride on auro-aure sulphide would require for their neutralisation a considerable thickness of rock.—H. K. T.

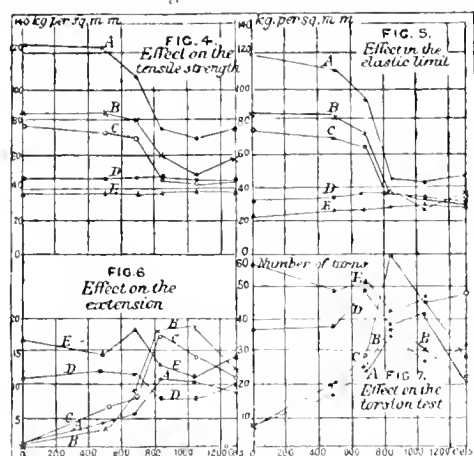

The Influence of Heat upon the Properties of Iron and Steel Wire. M. Rudeloff. Mitt. König. Tech. Versuchs. 1891, 109—140.

The material used for the purposes of the investigation was in the form of wire. Five samples were examined, three being wire ropes and two being telegraph wires. They had a tensile strength of 126.3, 84.7, 76.7, 45.1, and 36.3 kilos. per sq. mm. respectively (1 kilo. per sq. mm. = 1425.45 lb. per sq. in.), and were distinguished by the letters A, B, C, D, E. In order to ascertain what influence (if any) exposure to an elevated temperature in a lead bath had upon their chemical composition, analyses were made of three of the samples (A, B, and E) before and after they had been submitted to this treatment, with the following results:—

Heated to	Com-bined Carbon.	Silicon.	Man-ganese.	Sul-phur.	Phos-phorus.	Copper.
..	0.46	0.15	0.89	0.01	0.028	0.08
A. { 450°—560°C.	0.47	0.13	0.92	0.01	0.029	0.06
{ 780°—880°C.	0.32	0.17	0.96	0.03	0.021	0.05
..	0.15	0.04	1.10	0.03	0.093	0.04
B. { 450°—560°C.	0.17	0.03	1.09	0.03	0.095	0.04
{ 780°—880°C.	0.05	0.10	0.95	0.03	0.101	0.05
..	0.02	0.07	0.27	0.05	0.041	0.041
E. { 450°—560°C.	0.02	0.07	0.28	0.07	0.039	0.01
{ 780°—880°C.	Trace	0.08	0.28	0.07	0.041	0.02

Preliminary experiments were conducted to determine the best method of heating the test-pieces and the time during which it was necessary to subject them to the temperature of the lead bath. It was found that although the rapidity with which the full alteration in properties was produced, varied, yet a period of five minutes generally sufficed; this time was therefore taken for the rest of the experiments.

The result of these experiments is most compactly shown in the following tables of curves:—

INFLUENCE OF HEAT UPON THE PROPERTIES OF IRON AND STEEL.

The temperatures must be taken as approximate only.

Certain other experiments were carried out, both to confirm the results quoted above, and to determine the electrical and magnetic relations of the test specimens before and after heating; the conclusions arrived at are recorded below:—

(1.) The samples examined suffered no appreciable change by heating in a lead bath to 475° C. An alteration was first perceptible when the temperature reached 889° C., and was then confined to the diminution of the percentage of combined carbon. No lead was absorbed from the bath in any case.

(2.) The length of time during which the samples were exposed to a high temperature had an influence upon their tensile strength and extension, which varied with the character of the sample. The effect was the more marked the higher the tensile strength, but in all cases was complete in five minutes; in the case of sample A (crucible cast steel), although the chief change was effected in five minutes, yet a further alteration was perceptible in a second like period.

(3.) The tensile strength decreased as the temperature to which the test-pieces were subjected was increased, the conditions of time and method of cooling being the same. The effect of the heating was first perceptible at about 500° C., and in general was lower the higher the original tensile strength of the material. The change induced by heating was complete when the temperature reached 1,000° C. The extension and the number of turns in the torsion test increased with the increase of the temperature used, contrary to what was observed with the tensile strength. Exposure to a temperature somewhat under 500° C. merely caused an increase in the extensibility and homogeneity of the sample, wherefore it should be expected that in these respects galvanised wire should be superior to the uncovered material. The influence of an elevated temperature upon the extensibility of the wire was complete at about 900° C. It was found that of samples which suffered the same diminution of tensile strength by heating, the increase in ductility and extensibility was not necessarily similarly related when the origin and nature of the samples differed.

(4.) Exposure of the test specimens to a temperature of 800°—1,200° C. had but little influence upon their electrical conductivity: such influence as could be perceived appeared to be due rather to an alteration in the chemical composition of the samples than in their mechanical properties.

(5.) The temperature coefficient of the electrical conductivity and the magnetic moment of the samples decreased as the original tensile strength of the material increased. After heating, the temperature coefficient showed an increase which was greater the higher the tensile strength of the original material. (Compare Le Chatelier's

researches, this Journal, 1891, 373). The magnetic moment was but slightly affected by heating, the tendency being for it to increase. (Compare "Effects of Abnormally Low Temperatures on Structural Iron." This Journal, 1891, 1008.)—B. B.

Tempered Copper. B. Kirsch. Mittheil. Techn. Gewerbe-Museums, 1891, 261—267.

So-called tempered copper has been put upon the market by the Eureka Tempered Copper Company, samples of which were examined at the Versuchsanstalt für Bau- und Maschinen material with the following results:—

1. CHEMICAL COMPOSITION.

	Ordinary Copper.	Tempered Copper.
	Per Cent.	Per Cent.
Silver.....	0.025	0.025
Copper.....	99.930	99.981
Tin
Zinc
Iron	0.082	0.088
Aluminium
Arsenic	0.016	0.012
Phosphorus.....	0.017	0.018
Total	100.101	100.154

As will be seen from the foregoing analyses, the difference of tempered copper from copper of ordinary commercial quality, as far as its composition is concerned, is but slight.

II. MECHANICAL PROPERTIES.

The coppers of which the analyses are given above were mechanically tested, with the following results:—

	Strength in Kilos. per Sq. Mm.	Elastic Limit in Kilos. per Sq. Mm.	Extension per Cent.	Contraction in Area per Cent.
Tension, tempered	18.14	8.05	18.0	26.7
Tension, tempered	19.58	7.67	22.5	36.6
Tension, untempered....	16.30	7.13	21.0	36.6
Tension, untempered ...	17.17	7.08	22.5	35.7
Compression, tempered .	39.38	10.42	28.0	..
Compression, tempered .	37.20	9.93	26.8	..
Compression, untempered	33.12	9.62	27.4	..
Compression, untempered	36.21	11.20	27.6	..

* 1 kilo. per sq. mm. = 1425.45 lb. per sq. in.

The tests and analyses quoted above were carried out in America and are quoted for the sake of comparison with those performed at the Versuchsanstalt, which are as follows:—

(a.) **Modulus of Elasticity.**—The modulus of elasticity determined on a specimen tested in tension, was 10,050 kilos. per sq. mm. The modulus determined by compression test was 2,930 kilos. per sq. mm., with a load of 2.5 kilos. per sq. mm., and 1,020 kilos. per sq. mm., with a load of 7.2 kilos. per sq. mm.

(b.) *Tensile Strength.*

Test Pieces used.	Kilos.* per Sq. mm.
Sheet, 0·11 mm. in thickness	50·2
" 0·13 " "	67·9
" 0·55 " "	56·8
" 0·64 " "	53·4
" 1·19 " "	52·3
Wire, 0·59 mm. in diameter	31·8
" 0·80 " "	72·0
" 1·65 " "	52·0
" 2·60 " "	50·0
" 4·26 " "	47·6
Rod, 87 mm. in diameter.....	19·0

The last named specimen had an elastic limit of 8·1 kilos. per sq. mm. A compression test was made in which deformation began when the load had reached 8·1 kilos. per sq. mm. The load could be increased to 219 kilos. per sq. mm. without producing cracks, although the test piece, which was originally 30 mm. in height, had been shortened to 7·8 mm.

(c.) *Ductility.*—The extension given by the sheet varied between 0·2—2·0 per cent., while that of the wire was 0·1—0·2 per cent., and that of the rod 13·1 per cent., while the contraction of area at the point of fracture of the latter was 33 per cent. From these tests, as well as by winding tests with the wire, it appears that the material possesses great ductility.

The foregoing series of tests shows that tempered copper possesses properties that distinguish it from the ordinary material, its strength in pieces of small section being noticeably high, although that of larger test pieces is by no means remarkable, as it shows the tensile strength of only 19 kilos. per sq. mm., while ordinary commercial copper gives 20—25 kilos. per sq. mm. Castings made of it are of good quality, and its electrical conductivity is high.

PATENTS.

Improvements in Apparatus for Concentrating Acids. W. C. Herrens, Hanau, Germany. Eng. Pat. 2499, February 11, 1891. 4d.

See under VII., page 36.

Improvements in the Manufacture or Purification of Steel or Homogeneous Metal. J. H. Darby, Brymbo. Eng. Pat. 2673, February 13, 1891. 6d.

THE author has previously described a method for the recarbonisation of iron or steel (Eng. Pats. 418 of 1888, 20,586 of 1889, 4030 of 1890; this *Journal*, 1890, 1134; and 1891, 469) by the direct introduction of carbon (see also Eng. Pat. 6303 of 1891, below). The present patent is a modification for the purpose of obtaining steel as free as possible from sulphur, phosphorus, arsenic, and manganese. The material used is basic pig iron low in silicon and sulphur, and containing phosphorus and manganese. In carrying out the process the basic pig iron is first converted into soft steel in a basic-lined hearth or converter. Its average composition when tapped would be: sulphur, 0·02 to 0·04 per cent.; phosphorus, 0·03 to 0·05 per cent.;

silicon, nil; manganese, 0·15 to 0·25 per cent.; carbon, 0·07 to 0·12 per cent. This product is next charged with carbon, by the methods described in the above patents, up to 1 to 1·5 per cent., and is transferred to a second basic-lined open-hearth furnace. 10 to 20 per cent. of grey hematite pig is added, and when the charge is thoroughly melted, it is worked in the usual way with limestone, lime and iron ore additions, if necessary. The charge is then tapped and recarbonised to any required extent. A separate furnace should be used for the second operation, since if a furnace is used which has been employed for phosphoric heats, it will take several charges to wash out the phosphorus contained in the basic lining and adhering slag. It is found that in the second melting and working the charge works freely, and does not froth, as is usually the case with hematite pig iron.—H. K. T.

Improvements in the Manufacture of Steel. J. H. Darby, Brymbo. Eng. Pat. 6303, April 13, 1891. 4d.

IN the methods patented by the author for the direct addition of carbon (Eng. Pats. 418 of 1888, 20,586 of 1889, and 4030 of 1890; this *Journal*, 1890, 1134; and 1891, 469), considerable difficulty is experienced in bringing the carbon into contact with the metal without great loss through combustion. In the present patent the ground carbon is mixed with the pulverised silicon, aluminium, nickel manganese, or other alloy of iron which has always to be used, and the two are added together through the chute or other apparatus employed for the regular addition of the carbon. (See also Eng. Pat. 2673 of 1891, above.)

PATENTS.

A Method of Renewing and a Preparation for Firing Filaments in Incandescent Lamps. J. Möhrle, Munich, Germany. Eng. Pat. 16,613, October 18, 1890. 8d.

THE lamp is either divided longitudinally into two parts, or more usually pierced by an elongated opening with the help of a blowpipe. Through this opening the old filament is removed, the platinum wires cleaned, and a cement applied to their ends composed of pure carbon mixed to a paste with the solution of a salt of some metal that can be fused only at a high temperature, such as a saturated acid solution of platinum or copper. The ends of the filament are applied

to the cement-coated ends of the platins, and the joints hardened and rendered conductive by an electric current passed into each joint by one platinum wire, and led away by a copper wire temporarily introduced through the slit and pressed against the joint.—E. T.

Improvements in or Relating to Electric Accumulators. P. Lauber, Basle, Switzerland. Eng. Pat. 17,631, November 3, 1890. 8d.

THE inventor's battery, called an "Elektrothek," is to enable "any proportion of volts to ampères" to be obtained. A large number of lead plates are separated from one another by insulating frames so that a series of water-tight cells is formed, the whole resembling a filter-press open at the top, except that there is no liquid connection from cell to cell. In charging, a current is passed in at one end plate, through the whole series, and out at the other end one, each plate becoming positive on one face and negative on the other. The active material is retained in depressions or cavities in the faces of the plates. The number of plates depends on the voltage required, and their area on the rate of discharge.—E. T.

Improved Means and Apparatus for Separating Alkaline and Earthy Metals and other Products from the Salts of such Metals, or from other Substances containing them. G. J. Atkins and E. Applegarth, London. Eng. Pat. 20,768, December 19, 1890. 8d.

TAKING sodium chloride as an example, it is stated that oxygen and chlorine are liberated at the anode, that sodium hydrate is produced and dissolved in the liquid at the cathode, and that if the latter be of mercury, an amalgam of sodium and hydrogen will be produced. This amalgam, however, when concentrated, causes a very high back E. M. F., and therefore increases the cost of the process. To diminish this the inventors cause fresh mercury to be continually exposed as cathode, either by allowing fresh mercury continually to stream over the surface of the latter, or by causing the cathode, in the shape of an endless band, to be in continual motion, and to be constantly picking up fresh mercury and getting rid of the old.—E. T.

Improvements in or Appertaining to Mercurial Air Pumps. W. P. Thompson, Liverpool. From A. Raps, Berlin, Germany. Eng. Pat. 2969, February 18, 1891. 8d.

See under XXIII., page 60.

Improvements in Secondary Batteries. P. Goward, London. Eng. Pat. 7949, May 8, 1891. 8d.

THE positive electrode is a tube of lead enclosing a round perforated porous pot. A large number of Λ - or Ω -shaped incisions are made in rows round the lead tube so as to leave metallic tongues of these shapes. The space between the lead tube and the porous pot is packed with peroxide of lead, or with the finely-divided metal produced by pouring melted lead into cold water. When the packing has reached the first row of incisions the tongues of these are turned inwards, more layers of packing are added in the same way and bound in place by the metallic tongues till the whole space is full. The negative electrode is of zinc and rests in a tray of mercury. All parts are perforated to allow free circulation of the electrolyte, and bound together by bolts of suitable insulating material.—E. T.

Improvements in Electric Primary Batteries. T. J. D. Rawlins, Lymington, and A. Walker, Bristol. Eng. Pat. 9683, June 8, 1891. 6d.

THE electrodes are made in the form of vertical discs mounted on a spindle and are kept revolving. The lower parts only are immersed, and by the frequent exposure to the air, are prevented from polarising.—E. T.

Improvements in Galvanic Batteries. A. de Meritens, Paris, France. Eng. Pat. 10,977, June 27, 1891. By Internat. Convention November 28, 1890. 8d.

THE negative electrode is composed of a sheet of aluminium soldered or riveted to a sheet of lead. The positive metal is zinc and the electrolyte a mixture of two parts of sulphuric acid and one of nitric acid diluted with water. By local action between the aluminium and lead, the latter becomes coated with its sub-oxide. By the action of the cell this is reduced to metallic lead, only to be formed again by the local action. The cell gives a very constant current, and can easily give 25 ampères per square decimetre. Instead of aluminium, "plates of platinum or other metal unattackable by or possessing greater power of resistance to the action of the acids," may be employed. (See also Eng. Pat. 15,575 of 1891, below.)

Improvements in Means to be Employed in the Electrical Deposition of Copper and the Obtaining of Products from the Operation. T. Parker, Wolverhampton. Eng. Pat. 12,898, July 29, 1891. 8d.

IN the commercial deposit of copper, the solutions contain as impurities arsenic, iron, tin, bismuth, and antimony, and these are deposited with the copper if present in too large quantities, or if the voltage at the terminals of the bath should rise too high. To prevent this the electrolyte is passed through a series of baths, one of which has electrodes of only one-third to one-fourth the area of those in the other baths, so that the voltage at its terminals is raised. The foreign metals are here deposited readily, and the solution thus kept in normal condition for the other baths.

The deposit removed from the vessels consists chiefly of copper sulphide, silver, gold, and bismuth. It is roasted and then treated successively with dilute sulphuric acid to remove the copper, hot concentrated sulphuric acid to remove the silver, and potassium cyanide to remove the gold. The separate solutions thus obtained are electrolysed for the recovery of the metals they contain.—E. T.

Improvements in Methods of and Apparatus for giving Increased Life and Efficiency to Arc Light Carbons. N. M. Garland, New York, U.S.A. Eng. Pat. 14,379, August 25, 1891. 8d.

A hood or sleeve made of metal at its upper part and of refractory porcelain or such material at its lower part, is fitted over each carbon, so that only the pointed parts of the hot ends are free. Many devices are described for maintaining the position of these sleeves. Their object is to hinder the combustion of the carbons, and to lessen the resistance of the lamps by leading the current as directly as possible to the points of the carbons. There are 37 claims.—E. T.

Improvements in Galvanic Batteries. A. de Meritens, Paris. Eng. Pat. 15,575, September 14, 1891. 8d.

THIS patent (as in Eng. Pat. 10,977 of 1890, abstracted above) relates to methods of eliminating polarisation by constructing the negative electrode of two metals of different potentials in the liquid. Platinised lead is more especially referred to, the platinum coating only extending over parts of the lead. The lead is the negative electrode to the zinc, and is prevented from polarising (as in the above-mentioned patent) by the local action which takes place between it

and the more negative metal platinum. Various designs for electrodes and complete batteries are described in the specification.—E. T.

An Improved Galvanic Battery. C. U. Fisher, London. From R. H. Thompson, New York, U.S.A. Eng. Pat. 15,597, September 15, 1891. 6d.

The point of the invention is the construction of negative electrodes of carbonised fibrous material such as rattan. The material is used in the form of rods or in a spiral, but the inventor prefers the former. When rods are employed the ends are placed in a groove in a carbon plate, which forms the top of the cell, by a cement composed of powdered coke, lamp-black, and asphaltum, the whole being then carbonised together. The fibrous carbon is said to be mechanically preserved from polarisation by its corrugated surface and porous nature, and the whole cell to be better in this respect than a Leclanché cell.—E. T.

Improvements in the Method of Making the Plates or Elements of a Secondary or Storage Battery. S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 15,621, September 15, 1891. 8d.

The inventor preferably employs as electrodes rods or wires of lead enclosed in a porous or fibrous covering, such as braided asbestos. These are rapidly formed by being made anodes in a solution of lime chloride, the lead chloride thus produced being held in place by the covering. The lead chloride can then be reduced to spongy lead by making the plates cathodes in the tanks and passing current for a sufficient time.—E. T.

Grape-Seed Oil and its Technical Application. F. M. Horn. Mittheil. Techn. Gewerbe-Museums, 1891, 185—187.

The oil obtained from dried grape-seeds by extraction with a mixture of ether and alcohol has been examined by the author, with the following results:—

Specific gravity at 15°	0.9561
Fatty acid content (Hehner's number).....	92.13
Acid number.....	16.2
Saponification equivalent.....	178.4
Volatile fatty acids (per cent.)	0.46
Iodine number.....	94.05
Glycerin content (per cent.)	8.87
Acid number of fatty acids	187.4
Iodine number of fatty acids	98.05
Acid number of acetylated fatty acids	137.1
Saponification equivalent of acetylated fatty acids ..	281.6
Acetyl number	114.5

The oil dissolves at a temperature of 70° in an equal volume of acetic acid of sp. gr. 1.0562, the solution on cooling becoming turbid at 66.5°. It is only partially soluble in alcohol, but dissolves readily in ether. It gives the claudin reaction. Its close resemblance, chemically and physically, to castor oil, suggested its possible utilisation for the manufacture of Turkey-red oil. A small quantity of that product was, therefore, prepared by the action of concentrated sulphuric acid (1 part) on the oil (4 parts), and subsequent washing and neutralisation with ammonia (2 per cent.), a sample of castor oil being simultaneously treated in the same manner. The two preparations were then tested with regard to their comparative values for Turkey-red dyeing, and the resultant shades found alike in all respects.

Grape seeds may be obtained in considerable quantity in the wine-manufacturing districts on the Continent, and since they contain up to 20 per cent. of oil, the extraction of the same should prove highly remunerative.—E. B.

Application of Alizarin-lakes for Colouring Candles, &c. G. Ulrich. Mittheil. Techn. Gewerbe-Museums, 1891, 198—202.

In the course of a research on the constitution of the Alizarin-red lake, it was discovered that the Alizarin colour-lake prepared by dyeing aluminium oleate of the composition $\text{Al}_2\text{O}(\text{OH})_2(\text{C}_{18}\text{H}_{33}\text{O}_2)_2$ (obtained by double decomposition between potassium oleate and aluminium sulphate), is soluble in beeswax, paraffin, and ceresin, and is, consequently, well-adapted for colouring candles, &c.

As aluminium oleate does not melt at the temperature of boiling water and, therefore, does not dye well with alizarin, &c. it is better, before dyeing, to render it fusible in hot water by melting it with an equal weight of wax. The dyeing is accomplished by suspending in hot water the mass so obtained, and adding alizarin, &c. until it is sufficiently dyed, the bath being then allowed to cool and the solidified cake removed, washed with water, and dried. Colour-lakes were prepared in this way from Alizarin, Alizarin-orange, Alizarin-green, and Alizarin-yellow. The dark-coloured mass obtained by dyeing in this manner with alizarin, when diluted with from 30 to 120 times its weight of wax, gives dark to medium shades of red; with still further dilution, pinks. The presence of the alumina lakes does not interfere with the combustibility of the candles, &c., provided the amount present does not exceed 12.5 per cent.

Aluminium ricinolate is unsuitable for the manufacture of lakes for the above-mentioned purpose, as it separates on cooling from its solution in wax.—E. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

"Argentine." A. Harpf. Papier-Zeitung, 1891, 16, 2584—2585, 2612—2614 and 2640—2642.

PATENTS.

Improvements in the Production of "White Lead" or Basic Carbonate of Lead and Apparatus therefor. R. W. E. MacIvor and Watson Smith, London. Eng. Pat. 16,093, October 10, 1890. 8d.

In this process finely-powdered litharge is added to a solution of ammonium acetate while the latter is being circulated by means of a pump through a "digestor" and a "heater." By this means, it is claimed, the litharge is rapidly dissolved by the ammonium acetate, with production of tribasic acetate of lead, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2 \text{PbO}$, and free ammonia. The temperature to which the solution is raised depends upon the strength of the ammonium acetate solution employed, the temperature ranging between 60° and 100°C . As soon as solution is effected the liquor is filter-pressed, the red lead and other coloured impurities from the litharge being left behind in the press while the clear solution of tribasic acetate of lead passes through a cooling system (when, if the solution be strong enough, partial crystallisation will take place) to the carbonator, where it is suitably treated with carbonic acid, for the conversion of the tribasic acetate of lead into a basic carbonate of lead. The basicity of the product is ensured by the presence of the free ammonia, which acts as a carrier of carbonic acid, the free ammonia becoming first converted by the carbonic acid into ammonium carbonate, which reacts with the tribasic acetate of lead to form basic carbonate of lead and ammonium acetate for use over again. To prevent over carbonation the carbonation is stopped while the liquid is still faintly alkaline. In this way, a white lead of great purity and basicity is obtained (see below).—O. II.

A New Product possessing the same, or nearly the same Properties as Spirits of Turpentine. T. Drake, Huddersfield. Eng. Pat. 16,916, October 23, 1890. 4d.

PETROLEUM spirit, shale naphtha or similar hydrocarbons are treated in a suitable vessel with a current of air preferably dried by passing over lime, whereby a product is said to be obtained having practically the same properties as spirits of turpentine extracted from pine-wood, and which may be used for similar purposes. Or, 40 per cent. of the said spirit is distilled off, thus increasing its specific gravity, and then treating the residue with chlorine gas until its specific gravity is brought up to 0.900 to 1.050. The acid formed in the treatment is removed by first blowing air through the chlorinated liquid and then washing it with sodium carbonate or with any suitable alkali or alkaline earth which is afterwards separated from the liquid "by any well known chemical process or processes."

—C. A. K.

Improvements in Copying Inks, Copying Books, and Appliances. H. Beales, Bristol. Eng. Pat. 17,373, October 30, 1890. 4d.

THE ink, which is said to copy effectively without water, brush, or press, is prepared with softened water, logwood, sulphate of iron, nut-galls, gum arabic, glycerin, cloves, and vegetable black. The inventor states that copies of letters and other documents written with this ink may be taken on ordinary press-copy tissue paper, by merely laying the hand on the tissue paper superposed on the writing, and drawing the hand over the same. The invention also relates to a specially prepared pad for steadying letters when laid for copying, consisting of a sheet of india-rubber stretched on cardboard.—E. G. C.

Improvements in the Manufacture of Basic Carbonate of Lead or White Lead. Watson Smith and W. Elmore, London. Eng. Pat. 19,323, November 27, 1890. 6d.

WHEN crude or impure litharge is used for the production of white lead as described in Eng. Pats. 10,426 of 1888, 6815 of 1889, and 16,093 of 1890 (this Journal, 1889, 552; 1890, 630; and above) the solution of tribasic acetate of lead

frequently contains copper and traces of iron, &c., which by repeated use of the ammonium acetate for dissolving fresh quantities of litharge gradually accumulate, and even if the precaution as described in the above patents be adopted of not quite fully carbonating, yet the last portions of the white lead precipitated are likely to be coloured brownish or yellowish. To avoid this discolouration, the carbonation is carried out (according to the amount of impurities present and as determined by previous laboratory experiment), so long as possible without precipitating the impurities along with the white lead. After removal of the highly-basic and pure basic carbonate of lead, the solution is carbonated as usual for the production of an inferior quality of white lead. By adopting these precautions, litharge containing considerable quantities of copper, rendering the litharge otherwise worthless for the purpose, can be used for the production of a white and highly basic white lead, the copper being retained in solution by the ammonia till near the completion of the carbonation.—O. II.

Production from Mineral Oils of Sulphonic Acids and Sulphones, and the Manufacture of a New Product by Treating Gelatinous Matters with Sulphonic Acid. A. M. Clark, London. From the "Gewerkshaft Messel" Grube Messel, Germany. Eng. Pat. 19,502, November 29, 1890. 6d.

See under III., page 22.

Improvements in the Manufacture of Basic Carbonate of Lead or White Lead. Watson Smith and W. Elmore, London. Eng. Pat. 19,784, December 4, 1890. 6d.

THE improvements relate to the purification of the ammonium acetate solution used for dissolving litharge in the production of basic carbonate of lead, when by repeated use for dissolving cupreous litharge it contains considerable quantities of copper. For this purpose carbonic acid is passed into the solution after the removal of the white lead fractions, as stated above in Eng. Pat. 19,323 of 1890, until all the remaining lead, or all but traces, is precipitated, when the solution is made slightly acid with acetic acid, and treated with finely-divided zinc or lead; or an electric current is passed through the solution either when acid or when slightly alkaline, electrodes of carbon or other suitable material being employed.—O. II.

Improvements relating to the Manufacture of Carbonate of Lead or White Lead, and to Apparatus therefor. W. Astrop, London, and F. H. Parker, Gravesend. Eng. Pat. 684, January 13, 1891. 6d.

THE "required quantity" of an alkaline carbonate is melted in a pot, and molten lead added to it and mixed; the pot is then removed from the fire and the mass poured out on the floor. It is then allowed to cool and sprinkled occasionally for about 48 hours with water, during which time it absorbs carbonic acid gas from the atmosphere. The product is thrown into a tank, washed, and the white lead filtered off, the alkali being recovered from the liquors by means of evaporation. The white lead formed is friable, and does not require grinding, and the patentees claim that their process is not injurious to health. There are five claims.

—F. H. L.

Improvements in or relating to Laundry Blue. J. Knowles Bolton. Eng. Pat. 13,429, August 8, 1891. 6d.

THE blue is pressed into moulds of such a form that the blocks possess corrugations or ribs on the surface, so as to expose a larger surface to the action of the water during use in washing, by which artifice it becomes possible to compress them more strongly than usual and lessen the tendency to "speaking."—F. H. L.

An Improved Anti-Fouling Composition for Ships' Bottoms.

A. McCowatt, Belfast. Eng. Pat. 14,160, August 21, 1891. 4d.

THE ingredients and approximate proportions used are the following:—(solids) oxide of zinc, 56; oxide of iron, 2·75; acetate of copper, 3·2; arsenic acid, 15·5; sulphur, 16·15; sulphate of manganese, 5·3; and camphor, 2; (liquids) boiled linseed oil, 16·4; coal-tar naphtha, 12·5; shale spirit, 14·2; turpentine, 23; colophony, 12·1; gum, 10·5; gutta-percha (crude), 9·1; and tallow, 2·2.—E. G. C.

Improvements in the Manufacture of White Lead. J. C.

Fell, London. From C. A. Stevens, New York, U.S.A. Eng. Pat. 16,098, September 22, 1891. 6d.

IN the manufacture of white lead, electricity has already been employed (J. K. Kessler, U.S. Pat. 292,119 of 1884, and T. D. Bottome, U.S. Pat. 414,935 of 1889), metallic lead having been "decomposed in an alkaline electrolyte into an oxygen-bearing salt of the metal, after which an attempt is made to convert the said salt into hydrated lead carbonate by the introduction of carbon dioxide into the electrolyte." A leading feature of this invention "consists in making the oxygen-bearing salts of lead insoluble in an acid electrolyte after their formation under the influence of an electrical current, by rendering the electrolyte neutral or nearly so, in which condition practically all of the hydroxide of lead present will be converted into hydrated lead carbonate upon the introduction of carbon dioxide." The following is a *précis* of the steps in the process of manufacture:—"The electrical decomposition of metallic lead in an acid electrolyte into an oxygen bearing salt of the metal, the neutralisation of the electrolyte after it has become charged with the oxygen-bearing salts of lead, and the conversion of the said oxygen-bearing salts into hydrated lead carbonate, and the precipitation thereof by the introduction of carbon dioxide either free or combined with the electrolyte."—E. G. C.

Improvements in the Manufacture and Production of Colouring Matters. C. Dreyfus, Manchester. Eng. Pat. 17,635, October 15, 1891. 4d.

See under IV., page 29.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Manufacture of Tanning Liquors and Extracts. F. Jean. Monit. Scient. 1891, 5, 913—918.

THE high prices following the war of 1870 allowed foreign leather to obtain a firm footing in the French market, and ever since the native tanner has been endeavouring to overtake his competitors. To this end hemlock, chestnut, quebracho, mimosa, and spurge-laurel (*Daphne Laureola*), or extracts thereof, have been largely substituted for the more expensive oak bark. Unfortunately the fawn colour of oak-tannage is regarded by the purchaser as a criterion of the quality of the leather, and it is only by careful mixture of the above substitutes with oak bark that the inferior colouration which they impart to the leather can be sufficiently avoided. According to the author, the English and American tanners can tan leather in six or even three months, which by the French oak tannage in pits requires one and two years for production, because, not having to pay so much attention to the colour of their goods, they can employ a greater diversity of tanning materials and stronger extracts.

There is no doubt that although for some years past mixed tannages of chestnut, quebracho, mimosa, divi-divi,

and myrabolams with oak have been successfully employed, yet the French tanners have a deep-rooted dislike for the use of extracts. This is probably due to the fact that, notwithstanding the care with which such extracts may be made, the tanner finds it unsafe to use a tannage of whose origin, applicability to his special purpose, and accompanying colouring and other extractive matters he is necessarily ignorant.

But the utility, as a means of shortening the tanning process, of being able to add to the tannage, at a given moment, a liquor far richer in tannin than such as can be obtained in cold leaches, is now generally acknowledged. It is with the view of enabling tanners to make their own extracts of the required strength that the author has designed the apparatus here described. The fault of most extraction processes is that they are conducted under conditions favourable for the solution of much colouring and resinous matters and of substances resulting from the decomposition of the wood by action of too high a temperature and of air.

AUTOMATIC EXTRACTOR.

The automatic extractor consists of a wooden digester C.C. of about 5 cubic metres (176·6 cub. ft.) capacity, with a chamber A underneath it and communicating with it by means of the tube c, which descends to within 3 cms. (1·2 in.) of the bottom of A, and has a mushroom sprinkler h fixed on to the top end. The copper is connected with a vat B of about 3 cubic metres (106 cub. ft.) capacity, and with another vessel T. The siphon S allows of the drawing off of the liquid in the copper into the chamber A. The doors P and P' are hermetically sealed, and are opened only when fresh tan is to be inserted or spent tan removed. The tube m m, pierced with holes, distributes water from the pipe p.

1,000 kilos. (1 ton) of tan are introduced through the door P, which is then screwed down; water is allowed to flow in through m m until the tan has absorbed as much as it will and the water stands at the level of the top of the siphon S. The valve S' allows of the escape of air during the influx of water. After one or two hours' maceration the cocks r, r' and c are opened; the siphon fills itself, and all liquid above the level of e siphons into A—say about 250 litres (55 gallons)—the air in A being forced into B and through the valve S''. The cock r'' is now closed, and a current of steam passed through the coil v v fixed in A at two-thirds of its height. This vaporises some of the liquor in A, and causes sufficient pressure to force the liquid up the tube c (the valve s closing the siphon) back into the copper. When it has all passed over, the vapour in A follows, it escapes through S', and relieves the pressure; the valve s opens, and the liquid is once more siphoned over. This alternate action goes on automatically, the

volume of the water evaporated being made good by addition of low pressure steam from the vessel T, fed from a generator, or by water through the sprinkler pipe *m m*. When the density of a sample drawn from *o* no longer increases, extraction is complete, and the whole of the liquid contents of the copper are drawn off into the vat B.

The water retained in the tan will amount to two-thirds of the total added, and therefore two-thirds of the tannin dissolved will remain in the copper after it has been thoroughly drained into B. To displace this the cock *r* is closed and *r'''* opened; a slow stream of water is then allowed to flow through the sprinkler *m m* until two-thirds of the quantity originally used have passed. This will, of course, give a weaker liquor, which can either be mixed with the first quantity or used on a fresh quantity of tan in order to obtain a doubly strong liquor; to do this, the spent tan is raked out through P', fresh tan substituted for it through P, and the cock *r* opened. This allows some of the liquor in B to flow into A; here it is heated by the lower steam coil *v' v'*, and forced by the pressure of its vapour back into the copper; thus the intermittent extraction begins again and continues as before.

Figures are given in the original to show what sort of extracts may be expected from such an apparatus. One which would not occupy more than 2 sq. metres (21.5 sq. ft.) would easily yield, in 10 hours, 12,000 litres (2,640 gallons) of strong liquor.

The author recommends the use of oxalic acid for the removal of lime salts from hard water which is to be used for making tanning extracts, a slight acidity being favourable to the subsequent extraction. He also suggests the addition of hydrofluoric acid in small quantity to extracts in order to make them antiseptic and discourage the growth of harmful mycelium. The amount necessary is so small as to be in no way harmful to the skins while tanning.

The concentration of extracts until they solidify is best done by steam heat under diminished pressure.

The economical decolourisation of tanning extracts is a problem yet to be solved. Gondolo's method reduces the colour to a honey-yellow, and is often employed. It consists in neutralising the extract, adding blood, and raising the temperature, whereby a coagulum containing tannin albuminate and colouring matter is thrown down. Other methods are here mentioned. They are similar to those employed for decolourising other liquids, and are all objectionable as removing some of the tannin.

The analysis of a tanning extract should include:—(1) density; (2) substances insoluble in cold water, which should not exceed 2 per cent., except in quebracho extract, which may have 3—4 per cent.; (3) acidity, organic and mineral; (4) contents of tannin and gallic acid; (5) substances extracted by hide; (6) extractive matters; (7) substances possibly added to increase the density. To form some opinion of the extent to which the extract will colour the leather, some of it, diluted to $\frac{1}{2}$ B., may be macerated for 12 hours with pieces of unhaird skin plumped in water. After another maceration for 18 hours in a fresh portion of extract, the samples are exposed to the air and compared with standard samples prepared from known extracts. Bands of mordanted calico might be used for ascertaining the nature of the astringent matters in the extract, as suggested by Villon (compare this Journal, 1890, 820, 1157; 1891, 803 and 863).

The paper concludes with some remarks as to the position of tanning as a French industry.—A. G. B.

Chestnut Wood Tannin. H. Trimble. Jour. Franklin Inst. 1891, 132, 303—307.

Castanea vesca (Linn.) is a large tree of rapid growth, found in many parts of the United States. An extract of its wood and bark has been used in the United States and in France for many years, being especially useful in tanning, where it corrects the reddish colour of hemlock (see preceding abstract), and in dyeing, where it gives a dead black with iron salts. Extract of chestnut oak (*Quercus Prinus*, Linn.), is by no means the same, though doubtless often mixed with that of *Castanea vesca*.

The following analysis is of chips of the wood, free from bark, collected from a large tree about 40 years old, cut in August:—

	Per Cent.
Crystalline wax, melting at 50° C. soluble in hot 95 percent. and in absolute alcohol	1.03
Gallic acid.....	0.05
Resin.....	0.28
Tannin, extracted by absolute alcohol.....	3.42
Mucilage.....	1.15
Dextrin.....	1.89
Sugar.....	0.96
Tannin extracted by water	1.92
Pectin and albuminoids	1.46
Extractive, dissolved by dilute acid.....	2.95
Ash.....	7.08
Moisture.....	7.05
Cellulose and lignin	70.76
	<hr/> 100.00

The gallic acid may have been formed during the drying of the chips; determinations of tannin in a separate portion of the wood by gelatin and alum, and by permanganate and hide powder gave, respectively, 7.86 and 7.85 per cent.

For the identification of the tannin 2½ kilos. of the finely-powdered wood were extracted with commercial ether (about 74 parts of ether, 26 parts of alcohol, and a little water) by percolation. The residue from the ethereal extract was dissolved in water, filtered, and precipitated in three portions by "lead oxy-acetate"; the precipitates were decomposed by hydrogen sulphide, and the solutions, having been freed from excess of that reagent, were shaken with ether. Gallic acid was thus extracted from each. The tannin from the middle fraction was precipitated by addition of common salt to the aqueous solution; it was washed with a saturated solution of salt and dried over sulphuric acid *in vacuo*, then dissolved in a mixture of ether and alcohol, rapidly filtered and evaporated. To completely purify it the whole process was repeated.

The following reactions of this tannin are identical with those of gallotannic acid; but as they differ somewhat from those already published, they are reproduced here:—

Ferrous salts.....	No change.
{ Ferric chloride	Blue-black precipitate.
{ Ammonia added.....	Purple precipitate.
{ Tartar emetic.....	Slight clouding.
{ Ammonium chloride added ..	Pale precipitate.
{ Copper sulphate	No precipitate.
{ Ammonia added.....	Light-brown precipitate.
Bromine water	No precipitate.
Lime water	White precipitate, turning light blue.
Ammonium molybdate	Yellow colour.
Sodium sulphide	No change.
Concentrated sulphuric acid ..	Light yellow.
Sulphuric acid (1 : 9)	No deposit.
Lead nitrate.....	White precipitate.
Cobalt acetate	Flesh-coloured precipitate.
Manganese acetate.....	White precipitate.
Uranium acetate.....	Crimson colour, turning dark red.
Ammonium picrate	No precipitate.
Potassium bichromate	Brown precipitate.
Ferric acetate.....	Blue-black colour and precipitate.
Alkaloids	White precipitate.
Gelatin	White precipitate.
Lead acetate.....	Light precipitate.

The ultimate analysis of the tannin also agrees with that of gallotannic acid; so the author concludes that chestnut-wood tannin is gallotannic acid.—A. G. B.

The Application of the Alpha-Sulphonic Acid of Naphthalene to the Bating and Puring of Hides and Skins.
P. S. Burns and C. S. Hull. *Technology Quarterly*, 1891, 4, 191—193.

AFTER the unhairing of skins and hides by liming it is necessary to subject them to some process for the removal of the lime which has been absorbed by the hide fibre in order to avoid the formation of tannate of lime when the hide or skin is immersed in the tan pit, and the consequent discolouration, slow tannage, and brittle leather. This is the object of the bating and puring processes, which have heretofore consisted in immersing the hide in an animal or vegetable putrescent or fermenting solution, the substances employed being hen, pigeon, or dog dung, sugar, glucose, and bran. Such bates are accompanied by and dependent upon the action of bacteria, which by the dissolution of the gelatin of the hide bring about its depletion, and allow of the removal of the lime by subsequent mechanical means.

The authors' experiments show that the removal of the lime is assisted by the carbonic and phosphoric acids, and their ammonium salts, and the formic, acetic, propionic, lactic, butyric, and similar acids contained in the putrescent solutions. The loss of gelatin from the hide in the bate was found by experiment to amount to a minimum of from two to three per cent. of the weight of the dry hide; this loss would be nearly doubled in the tanned leather owing to the fact that leather may be considered to contain half its dry weight of tannic acid.

The removal of the lime by some acid with which it will form a soluble salt is the obvious method for avoiding this unfavourable action of putrescent bate; but all mineral acids and most organic acids which form soluble lime salts cause the hide to swell up and assume a transparent and gelatinous appearance, rendering it useless for making most kinds of leather.

In α -naphthalene sulphonic acid an agent was found which removes the lime without mechanical aid, and leaves the hide soft and white without any loss of gelatin; it is, moreover, an excellent antiseptic, effectually preventing the action of bacteria. This sulphonic acid is sold for tanners' use under the name "Acridene Antiseptic Bating and Puring Acid."

Two lots of 150 individually marked calf-skins, alike in condition and character and each lot weighing 880 lb. in the hair, were limed and unhaired in the usual way; one lot was then bated in hen-dung drench, and the other in 3 per cent. solution of the α -naphthalene sulphonic acid. The lots were then mixed and tanned in the same vats, and afterwards sorted into the original lots. The skins bated with hen dung made 255 lb. of dry leather, weighing 395 lb. when stuffed; those bated with the sulphonic acid made 266½ lb. of dry leather, weighing 413 lb. when stuffed. The stuffing was the same in each case, so that the difference in the bate caused a gain of 4.55 per cent. in the finished weight of the leather. "It was also noticed

that the hen-dung skins were very apparently lighter in the flanks and shoulders than those bated with the sulphonic acid." The safety with which this bate may be placed in the hands of workmen, and the abolition of stench, are further recommendations for its use.—A. G. B.

PATENT.

Improved Artificial Leather. J. Sadler, Mistley. Eng. Pat. 1634, January 29, 1891. 4d.

LEATHER waste from carriers and glove makers is shredded into small pieces and mixed in a tank with Portland cement, lime, glue, and paste in the following proportions:—Leather waste, 14 lb.; cement, 1 lb.; glue, ½ lb.; lime, 2 oz.; paste (sufficient to make the composition workable) made with wheat flour.

This composition is placed in trays to obtain the necessary quantities for the size and thickness of sheet required; it is then turned into linen sheets and compressed between steel plates by hydraulic pressure amounting to 2 tons and upwards per square inch. The leather boards thus made are dried either by exposure to air or in an artificially heated room.

It is claimed that such leather substitute is superior to any as yet invented, and can be advantageously used for inner soles and heels.—A. G. B.

XVI.—SUGAR, STARCH, GUM, Etc.

Researches on the Gums of the Arabin Group. Part II. Geddie Acid, Geddia Gums, the Dextro-rotatory Varieties. C. O'Sullivan. *J. Chem. Soc. (Trans.)* 1891, 59, 1029—1075.

THE geddia gums consist of the calcium salts and small quantities of the magnesium and potassium salts of geddie acid, together with more or less albuminoid. Of the samples described, one contained but little nitrogenous matter, and the other two considerable quantities. Gum B. was diastatic, but did not invert cane sugar. The gums all dissolve easily in water, forming a yellowish or reddish syrup, which is neutral and dextro-rotatory.

The ash is separated by dialysing the acidified solution.

To obtain the pure gum acids, alcohol is added to the dialysed solution until a precipitate is produced; this is allowed to deposit and the clear supernatant liquid decanted. The addition of more alcohol produces a further precipitate, which is allowed to deposit, and so on until alcohol no longer produces a precipitate in the clear supernatant solution. By this method of fractional precipitation the whole of the albuminoid is obtained in the first precipitate; the other precipitates consist of a mixture of gum acids. The gum acids are separated from one another by repeating this fractional precipitation. The test of their purity is that a fraction on solution in water and fractional precipitation yields fractions possessing the identical optical activities and neutralising the same amounts of base. In this way the gum acids shown in the following table were obtained from two of the samples of geddia gum examined.

	Name.	Formula.	$[\alpha]_D$	Per Cent. of BaO in Barium Salt
Geddia gum I.	Tetr-arabinan-tri-galaetan-geddie acid	$4C_{10}H_{16}O_8, 3C_{12}H_{20}O_{10}, C_{23}H_{34}O_{19}$	+ 59	5.59
	Tri-arabinan-tri-galaetan-geddie acid	$3C_{10}H_{16}O_8, 3C_{12}H_{20}O_{10}, C_{21}H_{32}O_{17}$	+ 49	6.05
	Di-arabinan-tri-galaetan-geddie acid	$2C_{10}H_{16}O_8, 3C_{12}H_{20}O_{10}, C_{23}H_{34}O_{19}$	+ 43	6.75
	Mon-arabinan-tri-galaetan-geddie acid	$C_{10}H_{16}O_8, 3C_{12}H_{20}O_{10}, C_{23}H_{34}O_{19}$	+ 37	7.65
Geddia gum II.	Non-arabinan-tetra-galaetan-geddie acid	$9C_{10}H_{16}O_8, 4C_{12}H_{20}O_{10}, C_{22}H_{30}O_{15}$	+ 110	3.43
	Hept-arabinan-tetra-galaetan-geddie acid	$7C_{10}H_{16}O_8, 4C_{12}H_{20}O_{10}, C_{23}H_{34}O_{18}$	+ 100	3.53
	Pent-arabinan-tetra-galaetan-geddie acid	$5C_{10}H_{16}O_8, 4C_{12}H_{20}O_{10}, C_{23}H_{34}O_{18}$	+ 90	4.55
	Tri-arabinan-tetra-galaetan-geddie acid	$3C_{10}H_{16}O_8, 4C_{12}H_{20}O_{10}, C_{23}H_{34}O_{18}$	+ 80	5.40

The composition of any one of these gum acids may be represented by the general formula—

The gum acids which were soluble in the strongest alcohol were the most optically active and neutralised the least amount of base.

When an aqueous solution of any one of these gum acids containing 2 per cent. H_2SO_4 is heated at 80° – 100° for 10–30 minutes, the gum acid is hydrolysed to arabinon and a gum acid of lower molecular weight; the greater portion of the arabinon is at the same time hydrolysed to arabinose.

Under the above conditions the whole of the arabinan group is separated from the remainder of the molecule of the gum acid, and is hydrated to arabinon and arabinose, but by carefully restraining the reaction it is possible to obtain gum acids still containing a portion of the arabinan group.

The general reaction may be expressed as follows—

The gum acid may be easily separated from the sugar by precipitating the gum by alcohol, the alcoholic solution contains the sugar and sulphuric acid, the latter is easily removed by baryta and the neutralised filtered solution after concentration deposits crystals of arabinose.

On referring to the list of gum acids contained in the two samples of gum, it will be evident, that if any one of these from the same sample be hydrolysed according to the general reaction, the same gum acid will be obtained; but that the acids from different samples will be different. The following table shows the relationships of these gum acids with one another, and with that obtained from gum arabic under like conditions:—

Obtained by the Action of Sulphuric Acid on the Gum Acids contained in	Name.	Formula.	$[\alpha]_D$	Per Cent. BaO in Barium Salt.
Gedda gum III.	Penta-galactan-geddic acid	$5C_{12}H_{20}O_{10} \cdot C_{23}H_{38}O_{17}$	+ 30	6.51
Gedda gum II.	Tetra-galactan-geddic acid	$4C_{12}H_{20}O_{10} \cdot C_{23}H_{38}O_{15}$	+ 22	7.49
Gum arabic	Tetra-galactan-arabic acid	$4C_{12}H_{20}O_{10} \cdot C_{23}H_{38}O_{15}$	7.49
Gedda gum I. ..	Tri-galactan-geddic acid	$3C_{12}H_{20}O_{10} \cdot C_{23}H_{38}O_{13}$	+ 20	8.81

These gum acids closely resemble the natural gum acids. They are, however, less soluble in weak alcohol, but their most marked difference from the natural gums is their behaviour when their aqueous solution containing 2 per cent. H_2SO_4 is heated. They offer great resistance to the hydrolytic action of sulphuric acid, but they are hydrolysed slowly, the final stage being represented by the general equation—

The slowness of this reaction as compared with the rapidity of the first may perhaps be partly explained by the fact that in the latter both the gum residue and the sugar residue are hydrated; whilst in the former, it is only the sugar residue that is hydrated.

The sugar produced in the last reaction is all galactose; the gum acid, $C_{23}H_{38}O_{22}$, is difficult to prepare in quantities sufficient to accurately determine its properties.

It is easy to stop this reaction at any stage and obtain gum acids still containing the galactan residue. One of these, $C_{23}H_{38}O_{22} \cdot C_6H_{10}O_5$, has been carefully examined and appears to be identical with an acid obtained under like conditions from gum arabic, except that whereas the acid from gedda gum is strongly dextro-rotatory, that from gum arabic is inactive.

These gum acids are very soluble in alcohol of all strengths except the very strongest, and are dialysable.

—A. L. S.

l-Sorbitol. E. Fischer and R. Stahel. Ber. 1891, 24, 2141.

THE syrupy hexahydric alcohol, obtained in the reduction of *l*-gulose, when purified by means of its benzal derivative and dissolved in 7 parts of warm 90 per cent. alcohol, is, in course of eight days, deposited in warty tufts of small needles, retaining much water. These crystals, after drying for three days over sulphuric acid in vacuo melt at 75° , have the composition $C_6H_{14}O_6 \cdot \frac{1}{2}H_2O$, and in fact resemble ordinary sorbitol in all but its optical properties. The latter in saturated borax solutions containing 8.69 per cent. of sorbitol and having a sp. gr. 1.043, is slightly dextro-rotatory, turning the plane at 20° in a 20 cm. tube, 0.25° , the specific rotation being $[\alpha]_{20} = +1.4$, whereas the

substance under investigation is levo-rotatory to the same degree, and is therefore undoubtedly, as already suggested, *l*-sorbitol the optical isomeride of ordinary sorbitol.—D. A. L.

Chemical Composition of Vegetable Cell Membranes.

E. Schulze. Ber. 1891, 24, 2277–2287.

IN this communication the author not only introduces new researches, but also summarises previous work (see this Journal, 1890, 878, 956, 1143, and 1151). Firstly, as regards those carbohydrates which are readily extracted from vegetable cell membranes by hot dilute mineral acids; four of this kind, yielding on hydrolysis galactose, mannose, pentagucose, and arabinose respectively have been discovered in the cell walls of numerous plant seeds, for example in the seeds of:—yellow lupin (*Lupinus luteus*), soja bean (*Soja hispida*), coffee bean (*Coffea arabica*), pea (*Pisum sativum*), bean (*Faba vulgaris*), cocconut (*Cocos nucifera*), palm nut (*Elais guineensis*), *Phania dactylifera*, *Tropaeolum majus*, *Paonia officinalis*, *Impatiens balsamina* and in the seedlings of red clover (*Trifolium pratense*) and vetch (*Medicago sativa*) the first of these carbohydrates is found, whilst the second is present in a great number of seeds, but the third and fourth do not appear to be so widely or profusely distributed. These particular portions of the cell walls, which are so readily attacked by dilute acids, on hydrolysis yield, almost without exception, a mixture of glucoses.

Turning now to the portions of the cell membranes less readily attacked by dilute mineral acids, the so-called celluloses, four new ones, one from white deal (*Picea excelsa*), one from rye straw (*Secale cereale*), one from red clover (*Trifolium pratense*) and one from sesame (*Sesamum indicum*) seed cake have been investigated. The wood cellulose was prepared by the sulphite method, and before use was extracted by boiling for some hours with 4 per cent. hydrochloric acid. To prepare the others the finely rubbed material was exhausted with ether, then with very dilute sodium hydroxide, then boiled four or five hours with 4 or 5 per cent. hydrochloric acid, then treated with F. Schulze's reagent (cold dilute nitric acid and potassium chlorate), being finally washed with warm dilute ammonia, water, alcohol, and ether. All four yield dextrose on hydrolysis with strong sulphuric acid by Flechsig's method, and the author has already shown that celluloses derived

from lupin grain, pea seeds, lupin pods, wheat bran, coconut cake, and coffee beans also yield dextrose under similar treatment, while Flechsig has proved the same to be true of cotton cellulose, making in all 11 celluloses from which grape sugar has been obtained.

The next point investigated was the kind of sugar, if any, which was associated with the dextrose in the products of these hydrolyses.

In concluding remarks on the nomenclature of the different chemical constituents of vegetable cell membranes, it is suggested that the name "cellulose," if used without an adjunct, should signify the cell constituent which is only slightly attacked either by dilute mineral acids, dilute alkalis, or by F. Schulze's reagent, but which dissolves in ammoniacal copper oxide and yields dextrose on hydrolysis. If, however, the name "cellulose" be applied as a group-name, it is proposed to name the last-mentioned cell constituent dextroso-cellulose, and the cellulose-like compound which yields mannose on hydrolysis mannos- or manno-cellulose. It is not considered that the wood-gums are sufficiently investigated to be included in this scheme of nomenclature. Hemicelluloses is the generic name proposed for those cell membrane constituents which are so readily converted into glucoses by the action of dilute mineral acids, whilst the individual carbohydrates are to be named galactans, arabans, xylans, &c., according to the sugar produced by the hydrolysis; and when two sugars are produced, such names as galacto-araban, galacto-mannan are to be used. Varieties can be distinguished in the usual way by the use of α , β , γ , "meta," and "para."

Of all the vegetable cell membrane constituents, the semi-celluloses are characterised by the readiness with which they are attacked by reagents; the action of hot dilute acids has already been noted. Lifschütz's mixture of sulphuric and dilute nitric acids appears to destroy them completely even in the cold. They dissolve readily when heated with dilute alkalis, being converted into a soluble variety; moreover, 5 per cent. sodium hydroxide attacks them, although but slowly.—D. A. L.

Organic Acids from Beetroot Juice. E. O. von Lippmann, Ber. 1891, 24, 3299—3306.

THE author has already stated that the lime precipitates which form in the evaporating apparatus, more especially at the commencement of the *campagne*, and in dealing with unripe roots, frequently carry down with them malic and tartaric acids, besides numerous other organic acids; the present communication is a summary of his results.

The acids, obtained from the crude calcium salts, were repeatedly converted into the lead salts and again decomposed into the acids. Ordinary levo-rotatory malic acid and dextro-rotatory tartaric acid were separated by crystallisation, and glutaric acid by taking advantage of its solubility in ether; the latter has not hitherto been observed as a constituent of vegetable products, and its occurrence is of especial interest in the present case on account of its close relationship to glutamic acid, to glutamine, and to α -hydroxyglutaric acid, the first being present in beetroots, whilst the two latter have been found in molasses (Ber. 1882, 15, 1156). The α -hydroxyglutaric acid from molasses has a specific rotation $[\alpha]_D^{19} = +1.76$, whereas that examined by Ritthausen (J. prakt. Chem. [2], 5, 351) had a specific rotation $[\alpha]_D = -1.98$; the two are, therefore, optical antipodes. Two sediments obtained also at the commencement of the *campagne* by heating the lined juice were next examined; besides oxalic acid, which represented the chief portion of each, succinic acid and a small quantity of normal adipic acid were separated from one sediment, the former by its sparing solubility in ether, the latter by its ready solubility in the same solvent; whilst from the other sediment glycollic acid was obtained by extraction with ether and purification of the lead salt. During the filtration of the juices at the same period of the year, a white substance is sometimes precipitated, and the precipitation is in some cases accompanied by the evolution of ammonia. Some of this substance was found on examination to be insoluble in water, alcohol, ether, and every solvent tried; after washing with water it had a dull white

appearance, a neutral reaction, did not contain nitrogen, and only left a very small quantity of ash on incineration. On boiling it with water glycollic acid was formed, and, judging from the latter, as well as from the numbers obtained by an elementary analysis it is identical with H. Schiff's hexaglyoxal hydrate, $C_{12}H_{12}O_{12} + H_2O$ (Annalen, 172, 1). The author has on one occasion separated glyoxylic acid from the juice of unripe roots.

Of the acids mentioned in this communication, succinic, glutaric, and adipic acids belong to the oxalic series, whose first five members have now been recognised in beetroot juice; glycollic and glyoxylic acids are closely related to oxalic acid, malic and tartaric acids to succinic acid. As it can no longer be doubted that aldehydes are the first assimilation products of the plant, it seems probable that such condensation products as hexaglyoxal hydrate (see above) are formed from these, which in their turn yield acids by hydrolysis. Finally, attention is drawn to the probability that the sugars may perhaps result by the condensation of glycollic aldehyde ($3 C_2H_4O_2 = C_6H_{12}O_6$), a compound which stands intermediate between formaldehyde and glyceraldehyde. Indeed, it seems probable that such a condensation might take place in the case of glycollic aldehyde even easier with formaldehyde. In view of Brunner's observations (Ber. 19, 595) on the wide dissemination of glyoxylic acid throughout the vegetable kingdom, this readily yielding glycollic acid on reduction, the question is well worthy of being submitted to further experiment.—A. R. L.

Studies on Yeast. J. Eilfont. Monit. Scient. 1891, 5, 1137—1144.

IN a previous communication (this Journal, 1890, 1055; Monit. Scient. 1890, 449, 790, and 1013) the author has shown that hydrofluoric acid or the alkaline fluorides, in quantities of 5 to 15 mgrms. per 100 cc., prevent the development of harmful organisms without effecting the yeast or diastase.

In the present investigation, attention was more particularly paid to the effect of the fluorides on the various varieties of yeast.

The four varieties used were *Saccharomyces cerevisia*, *Pastorianus I.*, Carlsberg, and Burton.

It was found that quantities of fluorides greater than 100 mgrms. per 100 cc. very appreciably diminished the fermentative power of all the yeasts, and that 300 mgrms. per 100 cc. destroyed it almost completely.

If any one of these yeasts that has grown in a solution containing fluoride be grown in a solution containing none, it will be found to be more active than the original yeast, the activity being more marked the more fluoride was contained in the first solution. This is most markedly the case with Burton yeast and *Saccharomyces cerevisia*. By taking advantage of this phenomenon it is possible to separate Burton yeast from *Pastorianus I.* by growing the mixed yeasts in a wort containing alternately 300 mgrms. per 100 cc. fluoride and no fluoride, when after the experiment has been repeated three times, the final yeast will be found to be pure Burton yeast.—A. PATENTS.

Improvements in the Treatment of Cereals for Preventing or Arresting Decomposition, and for Preserving or Improving the Condition thereof. E. Luck, R. Pott, and N. Pott, London. Eng. Pat. 19,168, November 25, 1890. 8d.

THE object of this invention is to improve or preserve the condition of cereals and to prevent or arrest the deterioration thereof by moisture or by insects, &c. This purpose is effected by treatment with sulphurous acid, and it is claimed that by this means grain which has been damaged by moisture, but not excessively so, may be restored to its original colour and condition, and for most industrial purposes rendered equal to new.

The sulphurous acid is preferably employed in the gaseous state, and is produced by burning sulphur in a current of air. The gas is washed and dried by being passed through two vessels containing respectively water and pumice or some other suitable material soaked in strong sulphuric acid. Finally the gas is warmed by passing through a coil heated externally by means of hot air, water, or steam, and is conducted underneath a perforated floor on which the grain undergoing treatment is spread. When the grain has been sufficiently treated the burning sulphur is extinguished and air alone is forced through the apparatus. By this means the grain is dried and rendered fit for storage.

Instead of the gas a solution of sulphurous acid may be employed, either alone or in conjunction with some alkaline substance (such as lime or chalk), the cereal being steeped in the solution and afterwards dried, if required.

For drawings and details of the necessary apparatus the original specification must be consulted.—H. T. P.

Process for the Preparation of Hop Extract. A. Foelsing, Düsseldorf, Germany. Eng. Pat. 21,044, December 24, 1890. 4d.

THE hops are treated in a battery of diffusion apparatus with water at 60° C. under a pressure of $1\frac{1}{2}$ atmospheres. In order to render the extraction the more complete and to prevent the oxidation of the bitter principles of hops, about $2\frac{1}{2}$ per cent. of gum tragacanth is added to the water.

The extract is concentrated in vacuo to about $2\frac{1}{2}$ B.

—A. L. S.

Process and Apparatus for the Manufacture of Champagne and other Beverages charged with Carbonic Acid. F. König, Turin, Italy. Eng. Pat. 852, January 16, 1891. 8d.

THE apparatus consists of two air-tight vessels, in one of which the final fermentation takes place, while the other receives the clear sparkling wine. These vessels are connected by an air pipe at the top and by a liquor pipe at the bottom, filters of porous earthenware, cotton wool, or asbestos, &c. being fitted on the lower pipe.

The wine is introduced into the first vessel and the air remaining in both vessels replaced by carbonic acid gas. All communication with the external air is cut off; the upper pipe between the two vessels is left open and the lower one is kept closed.

After fermentation has gone on for some time, the upper pipe is closed and the lower one opened; as the fermentation proceeds the pressure increases in the first vessel and forces the wine through the filters into the second vessel, from which the wine is bottled.—A. L. S.

A Means of Collecting Hops or other Ingredients when Boiling or in Circulation in a Copper or similar Vessel. F. H. Fortescue, London. Eng. Pat. 12,077, July 16, 1891. 6d.

THE ordinary boiling or circulating fountain as fitted to wort coppers is fitted with a wire cage or strainer. The wort as it issues from the top of the fountain falls into the cage, which retains the hops and allows the clear wort to pass through.—A. L. S.

An Appliance for Distributing and Aërating Brewers' Wort. R. H. Leaker, Bristol. Eng. Pat. 17,681, October 16, 1891. 6d.

THE appliance consists of a trumpet-shaped tube, the narrow end of which is connected with the hop-back or copper. Just within the wide end is suspended a bell-shaped plate. The wort is discharged from the opening between the edges of the trumpet-shaped tube and the bell-shaped plate. The width of the opening is capable of adjustment; when the apparatus is fitted to the discharge pipe of a copper it is fairly wide to admit of the passage of the hops; when it is fitted to the pipe discharging from the hop-back on to the cooler, the opening is narrower and is partly self-adjusting by a spiral spring; in this case the bell-shaped plate is perforated with holes. The wort issues on to the cooler in a dome-shaped sheet and from the holes as a fine rain. The apparatus is said both to cool and aërate the wort.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Examination of Tin-plated Iron Articles used for the Preservation of Foods. J. Pinette. Chem. Zeit. 1891, 15, 1109.

THE attention of foreign importers of tinned foods is particularly called to the following law which has been in force in Germany since October 1, 1889:—

Tin used for the tin-plating of iron must contain no more than 1 per cent. of lead. The solder used for sealing these articles must consist of an alloy of tin, with no more than 10 per cent. of lead.

The author proposes the following easy process for the assay of such tin wares:—The material is (without touching the solder) cut into small pieces and heated in a porcelain dish with dilute nitric acid until the pieces look black. The liquid is then at once poured off, and the residue well washed to remove any adhering stannic acid. The whole is evaporated to dryness, and then again heated with nitric acid to separate the lead and also any iron. The stannic oxide is finally ignited and weighed. The lead is made into sulphate by evaporation with sulphuric acid, and after freeing it from iron by washing with dilute sulphuric acid, it is then collected and weighed as usual. As regards the testing of the solder, the author remarks that the different pieces of solder from the same tin may have a different composition.—L. de K.

PATENTS.

Improvements in Obtaining an Extract of Malt and Hops, and in Preparing a Confection of the Same. E. Sonstadt, Cheshunt. Eng. Pat. 21,006, December 24, 1890. 6d.

A wort is prepared from malt and water in the usual way, this is boiled with hops in a closed boiler, about 1 part of hops being used for every 10 parts of malt. A current of carbon dioxide is passed through the boiler, issuing with the steam. The mixture of steam and carbon dioxide is passed into a condenser, where the steam is condensed, and the carbon dioxide, carrying with it some hop aroma, is passed over fresh butter and ignited asbestos, in order to remove the aroma.

After the boiling has continued for some hours, the boiled wort is discharged and strained from the hops. The clear extract is concentrated in an atmosphere of carbon dioxide to the required concentration, and then cooled. The aroma-charged asbestos is boiled with the condensed water, the first portion of the distillate contains all the aroma, and

is mixed with the cooled extract; this is then bottled, sealed, and sterilised by being heated to boiling. If a solid extract is required, the concentration is pushed as far as possible, and mixed while hot with sugar, the "aroma-water" prepared as above and the aromatised butter.

Improvements in Apparatus for Testing the Quantity of Cream in Milk. H. E. Newton, London. From L. J. Augustenborg and R. Hansen, Kolding, Denmark. Eng. Pat. 14,797, September 1, 1891. 6d.

THE improvements claimed are in the construction of the rotating table described below, and in the warming of the space in which it rotates by means of a reservoir of hot water supported immediately above it. The rotation is accomplished by means of a worm on the vertical spindle, which carries the table, worked in a toothed wheel.

The table is furnished with a flange, to which are fixed blocks, the intervals between which are fitted with caoutchouc pads. Round the spindle in the centre of the table is a wooden disc, the circumference of which is covered with a rubber ring. The test tubes containing the milk are placed radially on the table between the rubber ring and the caoutchouc pads.—A. G. B.

An Improved Process for Preserving Eggs. B. J. B. Mills, London. From A. Micault de la Vieuville, Lyons, France. Eng. Pat. 17,717, October 16, 1891. 4d.

THE fresh eggs to be preserved are first washed in milk of lime in order to remove any surface dirt and grease, and also to destroy "the ferments which exist in the porosity of the shell." The eggs thus cleaned and purified are coated with a thin continuous layer of gelatin, obtained by plunging them into a solution of this material. The gelatin employed must be free from bad odour or taste, and should preferably be colourless so that the whiteness of the shells may not be impaired.

It is claimed that eggs thus prepared may be preserved absolutely unchanged for a year or more without any special precautions as regards aëration and temperature of storage. It is further stated that the shells of the eggs are rendered stronger by the treatment, so that increased facility in transport is obtained.—H. T. P.

XIX.—PAPER, PASTEBOARD, Etc.

The Sizing of Paper. J. Wunder. Chem. Zeit. 1891, 15, 702—703.

PAPER sized with rosin or wax easily becomes saturated with water, but if treated with animal size it is rendered to a certain degree waterproof. To effect this, paper is first passed through a solution of animal size, and then through a solution of aluminium sulphate and sodium acetate mixed in the proportions required by the following equation—

Instead of sodium acetate any other acetate in equivalent quantity, as well as other salts, e.g., sulphites, thiosulphates, chromates, &c., may be taken.

The method may be varied by adding the aluminium sulphate to the size solution, or by dividing the latter into two parts, mixing the one with the aluminium sulphate solution and the other with one of the above-mentioned salts. The final result may be rendered still more complete by drying the paper after having passed it through the first solution, and subsequently soaking it for about 12 hours in the second solution. Such papers are said to be waterproof to a high degree.—H. S.

Aluminium Sulphate. Papier-Zeitung, 1891, 16, 2326—2328.

Pure Neutral Sulphate.—A saturated solution at 15° C. of pure aluminium sulphate has a specific gravity of 1.341 and contains 36.60 grms. $\text{Al}_2(\text{SO}_4)_3$ or 10.99 grms. Al_2O_3 per 100 cc. If such a solution be evaporated until it has the same specific gravity (1.341) at the boiling temperature, it forms on cooling a magma of small crystals which cannot be completely freed from the mother-liquor by pressing, but they lose water by exposure to air. If the evaporation be carried further until the boiling point rises to 109° C., and the specific gravity at this temperature is 1.540, the solution solidifies on cooling to a hard mass, which is the usual commercial form of the sulphate, and contains 46.6 per cent. $\text{Al}_2(\text{SO}_4)_3$, or 14.0 per cent. Al_2O_3 . If the cooling be conducted rapidly the solid mass will be at first amorphous and quite white, but become crystalline after some time and lose somewhat in whiteness. If the solution cools slowly the resulting solid will be crystalline. Less evaporation gives a softer product and more evaporation a harder one, but at the same time it is more vitreous and therefore not so white in appearance; a product containing more than 15.5 per cent. Al_2O_3 persistently refuses to become crystalline. When the boiling temperature rises above 109° C., the solution becomes viscid and begins to froth, and for this reason, normal aluminium sulphate produced on the large scale cannot well contain more than 15.5 per cent. Al_2O_3 .

The following table gives the composition of the salt with different amounts of water:—

	Pure Aluminium Sulphate,			
	with 13% Al_2O_3	with 14% Al_2O_3	with 15% Al_2O_3	Crystallised with 18 aq.
Contains in 100 parts by weight,				
Al_2O_3	13.00	14.00	15.00	15.44
SO_3	30.29	32.62	34.95	35.98
$\text{Al}(\text{SO}_4)_3$	43.29	46.62	49.95	51.42
H_2O	56.71	53.38	50.05	48.58
	100.00	100.00	100.00	100.00

Aluminium sulphate dried at 95° C. retains 8 molecules of water, and contains 21.2 per cent. Al_2O_3 ; it is pure white in colour, can be easily ground to a fine powder, and is readily soluble in water to a clear solution. Aluminium sulphate containing 38 per cent. of water, corresponding to 18.6 per cent. Al_2O_3 , becomes after fusion perfectly transparent, clear, and brittle like glass.

Basic Sulphate.—A solution of the neutral sulphate can be diluted to any extent without precipitating, but the basic sulphates decompose on dilution. A solution containing 36 per cent. of $\text{Al}(\text{SO}_4)_3$ will allow of two-thirds of the acid being neutralised with caustic soda before a permanent precipitate forms; the same solution diluted 10 times gives a permanent precipitate when only one-third of the acid is neutralised with alkali.

Commercial Sulphate of Alumina.—The impurities of this product of special importance to the user are iron and free acid. The amount of iron varies between 0.003 per cent. and 0.5 per cent.; products containing less than 0.01 per cent. Fe are commonly distinguished as free from iron, and are used in dyeworks and in works producing the finer kinds of white paper. Dyers and leather dressers who object to these small quantities of iron continue to prefer alum. The commercial article contains iron in both stages of oxidation, and in varying proportions. For use in sizing good writing paper the percentage of iron may reach 0.15 per cent. without apparent disadvantage, and if all the iron is in the ferrous state the percentage may reach 0.3 without affecting the colour of the paper, but it is liable in this case to acquire a yellowish tinge on longer exposure to the air, especially under direct sunlight. An amount of iron exceeding 0.3 per cent. renders the sulphate of alumina applicable only for low-grade or coloured paper.

The quantity of free acid varies from 0.2 to 1.0 per cent. SO_3 , but is seldom above 0.5 per cent. It is not left in the free state on account of any difficulty in neutralising, but to give a better appearance to the article. Neutral or feebly basic aluminium sulphate containing 0.05 per cent. Fe as Fe_2O_3 is yellowish from the presence of basic ferric sulphate, and if the iron in the ferric state amounts to 0.15 per cent. Fe the colour is as deep as beeswax. If free acid were present this quantity of iron would scarcely colour the article, and if, besides, the iron were in the ferrous state no colouration at all would be perceptible, only a very feeble greenish tint being seen when the ferrous iron amounts to 0.5 per cent. A few tenths of a per cent. of free acid is usually of no importance, especially in the paper manufacture where a small quantity of free acid is of advantage for decomposing the resin soap.

A third impurity, which may at times be objectionable, is the residue insoluble in water: it rarely exceeds 0.3 per cent. Other impurities may be potash, soda, magnesia, chlorine, and nitric acid, but they are only occasional and are not detrimental. In one sample of second grade 2 per cent. of zinc was found, and this metal should be looked for in the alumina determination.

The commercial article usually contains from 13 to 15 per cent. Al_2O_3 .

The raw materials for aluminium sulphate are kaolin and bauxite. An English kaolin much used in Germany has the following composition after drying at 100° C.:—

	Per Cent.
SiO_2	45.3
Al_2O_3	39.9
Fe_2O_3	0.6
H_2O (combined)	13.0

The composition of bauxite is very variable. The following table gives the percentage composition of several kinds:—

	French.			Irish.		German.	
	a.	b.	c.	d.	e.	f.	g.
Al_2O_3	59.0	73.0	63.8	59.8	53.8	52.0	46.1
Fe_2O_3	8.0	1.5	6.7	17.9	1.6	1.6	15.1
SiO_2	16.6	16.5	6.3	1.5	8.7	12.0	10.4
TiO_2	5.8	6.2	4.2
Loss on ignition..	16.3	9.0	23.1	21.0	20.3	24.0	23.1
						24.7	

The methods of producing aluminium sulphate vary somewhat according to the materials and the degree of purity required in the product.

Kaolin is usually calcined at a low temperature, ground, finely sifted, and mixed with sulphuric acid of 1.45 sp. gr.

Steam is then injected to promote the reaction, which afterwards proceeds very violently. At the end of the reaction the mass will contain no free acid if the requisite excess of kaolin had been employed. It is dissolved in water to a specific gravity of 1.29, and is filtered. The filtrate is evaporated to the required extent and then allowed to cool and solidify. Uncalcined kaolin may be used, but the reaction must be then conducted under pressure of steam to secure its completion. The crude sulphate of alumina of commerce is the product of the above reaction, omitting the solution in water. It contains 10—12 per cent. Al_2O_3 as sulphate and 25—30 per cent. of insoluble matter (silica and undecomposed kaolin), besides 1 per cent. or more of free acid. It is used for the lower grades of paper, for which the insoluble matter serves as filling. It is also used for the clarification of waste waters.

Bauxite in a finely ground condition, without calcining, is mixed with sulphuric acid and the product of the reaction is treated as above, when a sulphate of dirty white appearance is produced containing 0.5 per cent. Fe. A simple method of separating the chief part of the iron is to treat the solution of 1.29 sp. gr. with bleaching powder or nitric acid to peroxidise all the iron, and to render the solution feebly basic. On allowing it to stand for some months the iron separates out, but not completely, as basic sulphate, accompanied by a little alumina. If it be required to reduce all the iron to the ferrous state to improve the appearance of the article, it is best done by boiling the solution with finely-powdered charcoal.

Another method of treatment is applicable to a raw material containing iron with but very little silica, such as the bauxites c, d, and h. The finely-ground bauxite is intimately mixed with soda ash and calcined at a low heat. The mass is extracted with water, to dissolve out the aluminate of soda. On treating the solution with carbonic acid gas the alumina is precipitated as hydrate, which is filtered off and treated with the requisite quantity of sulphuric acid for the production, without further evaporation, of a sulphate of 14 per cent. Al_2O_3 of great purity. The carbonate of soda left in the solution is recovered by evaporation.

Iron in aluminium sulphate is separated by precipitation with excess of caustic soda. The precipitate is collected on a filter, re-dissolved in sulphuric acid, reduced with zinc, and estimated by titration with permanganate solution.

Small quantities of iron are determined colorimetrically. Free acid is estimated by adding potassium sulphate to the solution and evaporating to dryness. The residue is powdered

and extracted with alcohol to dissolve out the free acid which is then determined by titration with decinormal alkali.

—G. H. B.

Papyrus. Papier-Zeitung, 1891, 16, 2528.

This article gives an account of the uses of the papyrus plant amongst the ancients. It is known to have been cultivated by the Egyptians as far back as 1800 B.C. The young plants were used as a foodstuff, and the old ones furnished material for baskets and other woven utensils. Its chief use was the manufacture of paper, which became an important industry on the banks of the Nile, where the papyrus grew. Papyrus paper was expensive, but very durable, rolls of it having withstood the destructive influence of many centuries at time. Papyrus was imported from Egypt by the Romans for the fabrication of eight different sorts of paper. The cultivation of the plant has now almost

entirely ceased, a last attempt during this century to manufacture papyrus paper in Syracuse having been unsuccessful.

—G. H. B.

"Argentine." A. Harpf. Papier-Zeitung, 1891, 16, 2584—2585, 2612—2614 and 2640—2642.

"ARGENTINE" consists of nearly pure tin in a very fine state of division, and is also called "tin-dust." It is used principally for ornamenting paper, such as silver paper, and is manufactured in only a few places, as the demand is small. The process of manufacture described is that carried on in Herdain, near Breslau. The materials required are tin,

hydrochloric acid, and zinc. Tin is used in the granulated form and also as it exists in all kinds of alloys, such as gun metal and white metal, the turnings forming the waste material of other factories being suitable. The turnings are placed in open copper vessels holding about 250 litres, and ordinary hydrochloric acid of 20° – 22° B. is added and boiled. As long as an excess of tin is present copper and antimony will not dissolve. The solution will contain chiefly tin and a little lead, and is run into wooden casks to cool, when most of the lead crystallises out as chloride. This is separated by filtration through sand, and converted into oxychloride by Pattinson's method for sale as a white pigment. The clear solution has a density of 33° – 40° B., and contains 17–23 per cent. Sn, with small quantities of lead and antimony. It is desirable that these impurities should be small in amount, as they are injurious to the colour of the product. The undissolved metal is exhausted by boiling three times with fresh acid, when it is washed and dried. On account of its admixture with antimony and metallic chlorides, this waste copper is not fit for castings, and is sold to a metal refiner. Not all the tin is removed by this process, as the metal residue retains about 2–3 per cent., the complete extraction of which would be accompanied by too much antimony and lead.

The next operation is the precipitation of the tin in wooden casks holding about half a cubic metre each. They are filled with water, and an iron basket well plated with tin and holding zinc scrap is suspended in each. Each cask receives twice daily an addition of $2\frac{1}{2}$ litres of the strong solution (about 40° B.) of tin chloride, which is thereby diluted to 200 times its volume. The metallic tin precipitated by the zinc from this dilute solution takes the form of a very light sponge, which is carried by adherent hydrogen gas to the surface of the solution, whence it is removed every morning, and well washed in a separate cask. It is then dried in a shallow oblong steam-jacketed zinc pan, in which it is moved about with wooden shovels. The dried dust is sifted in a rotating sieve provided with very fine meshes. It forms an extremely finely-divided metallic powder of a tin-grey colour. It consists of nearly pure tin with a very small quantity of lead and sometimes antimony. The output was about 500 kilos. per month, and its value was 280–300 marks for 100 kilos. of good quality. The liquor in the cask becomes gradually charged with zinc chloride, and is drawn off when its strength reaches 20° – 25° B. It is concentrated to about 50° B. by evaporation in enamelled cast-iron pans, and sold for preserving timber. An almost obsolete process for making silver paper involved the employment of a metallic dust prepared mechanically by grinding to powder an alloy composed of 96.5 per cent. of tin and 2.4 per cent. of zinc which was then mixed with a solution of glue and painted on ordinary white paper, a gloss being afterwards imparted by pressure. A genuine silver paper was also made by cementing silver leaf to paper with white lead and glue. By the modern process "Argentine" is employed and the cementing material is a "wax-solution" prepared in one of the following ways:—Four kilos. of ordinary beeswax and $\frac{1}{2}$ kilo. of potashes are boiled with 50 litres of water; or, 3 kilos. of starch are emulsified and boiled with 75 litres of water containing 5 lb. of beeswax and $1\frac{1}{2}$ lb. of potashes. 25 kilos. of "Argentine" are stirred into this solution contained in a rocking trough through which the roll of paper is caused to pass. The dull grey-coated paper is then passed through a hot calender under great pressure, which gives a high polish to the paper resembling tin-foil. Sometimes the calender is smeared with cocoa-nut butter, which increases the gloss and gives a greasy feel to the paper. A practical test of the quality of a sample of "Argentine" can be made by stirring it up with a little water and painting it evenly on paper with a brush. After drying the polish is given by rubbing the paper laid on a glass plate with a round piece of agate.

A considerable difficulty in the manufacture of the "Argentine" was occasioned by the appearance of small crystalline particles in the finished product, which had the effect of introducing irregular blotches into the silver paper. The author gives an account of experiments made for the purpose of finding a cause and a cure for these crystals, and

found that the precipitated tin sponge is liable to contain small crystalline needles of the metal when the tin chloride solution from which it is precipitated is insufficiently diluted, or when the zinc plates are contaminated with other metals in such a way that electrical currents are set up in the solution. Plates of tin and zinc connected by a copper wire and immersed in dilute tin solution caused the formation of crystalline needles of tin at the tin electrode, whilst the spongy metal separating at the zinc was free from crystals. Plates of zinc and lead employed in the same way gave similar results, and in this case impurities in the zinc plate were found to have a less effect on the result. As it is not possible in practice to employ pure zinc the author proposes to use a lead plate in electrical connexion with the ordinary impure zinc in order to obtain a tin sponge free from crystals. This modification of the process gave very satisfactory results as carried out in the following way. A wooden cask was divided into two compartments by a wooden partition containing a few holes to allow the solution to pass freely. Plates of lead and ordinary commercial zinc were placed in the separate compartments and connected by a copper wire. The cask was filled with water charged with 1 per cent. of the strong tin chloride solution (45° B.). The formation of sponge went on regularly and quickly at the zinc plate and was quite free from crystals, whilst only a few crystals of tin separated at the lead plate, which became covered with a dark-grey film. Large quantities of good sponge were obtained from successive additions of the strong liquor. The distinction between sponge and crystals must be taken as merely relative, for the microscope shows the sponge to consist entirely of very small crystals, which are not recognisable as such by the naked eye.—G. H. B.

French Straw-Paper. Papier-Zeitung, 1891, 16, 2611.

STRAW-PAPER has been in considerable demand in France and a good and firm article has been manufactured for the last 40 years. The process of manufacture has not in the meantime undergone much change. Chiefly rye straw is cut quite short in a cutting machine, and this chaff is heaped into large rectangular brick wells, where it is just covered with dilute milk of lime. A covering of heavy boards weighted with stones is put on, and the straw is left in this condition for two to four weeks, when it is taken out and worked under edge-runners for not less than an hour. Straw worked in this manner is harder than steamed straw and the knots are not softened, consequently the grinding must be well done. The straw now goes direct into the mill and after a short time into the pulp-vat. The French straw-paper machines are provided with shaking-troughs, knot-catchers, presses, and several drying cylinders.

—G. H. B.

Japanese Paper. G. Lauboeck. Mittheil. Techn. Gewerbe-Museums, 1891, 257–260.

FOUR samples of Japanese paper of a quality suitable for writing purposes were examined with the results shown in the table on next page.

The raw material from which these papers were made was derived from "Gampi" (*Wickstromia caulescens*) and "Kodsu" (*Broussonetia papyrifera*). Gampi gives a yellow colouration with an aqueous solution of iodine, while Kodsu becomes brown when similarly treated. The ends of the Gampi fibre are bulb-shaped and rounder; its width varies from 0.007 to 0.020 mm. When Gampi fibre is treated with an ammoniacal solution of copper oxide, it swells previous to dissolving, each fibre presenting the appearance of a string of beads, a reaction which may be considered characteristic.

The Kodsu fibre is of massive structure, and has a diameter of 0.014–0.031 mm. The fibres are partly covered with a very delicate colourless envelope which is most readily discernible at the end of the fibre; an ammoniacal solution of copper oxide acts less readily upon the Kodsu fibre than upon the Gampi fibre. The Kodsu

fibre is very flexible and strong, and its length averages 10—15 mm. All the papers examined, the results of which are recorded above, contained a little rice starch, but no other loading of any kind.

It is noteworthy that the first three samples largely excel the best European papers in strength, a circumstance the more remarkable as their thickness and weight are unusually small. It therefore appears that the good quality of Japanese paper is largely due to the length and fineness of the fibre from which it is made, though something must be ascribed to the rational method of manufacture and the personal skill of the artisans. The papers are not sized with rosin or with animal size, but with a vegetable preparation which does not unite the fibres firmly to each other, a circumstance to which the rough appearance of the surface of the paper may be ascribed. It will be interesting to see what will be the effect of sizing Japanese paper by European methods.—B. B.

The Alkaloids of the Areca-Nut. E. Jahns. Ber. 1891, 24, 2615—2617.

In a previous paper (this Journal, 1890, 1116) the author has pointed out that *arecoline*, one of the alkaloids contained in the areca-nut, when decomposed by acids or by alkalis, yields the base *arecaidine*. Further investigations have shown that this same body occurs in varying quantities ready formed in the areca-nut. It can be readily separated from the arecaidine with which it occurs by treatment with hydrochloric acid and methyl alcohol, when the arecaidine is converted into the methyl ester (arecolin) whilst the arecaidine forms a hydrochloride.

In addition to the alkaloids previously isolated it has been found that a new alkaloid, for which the name *Guvacine* (from the old Indian name for the areca palm—Guvaca) is proposed, occurs in varying quantity in several kinds of

areca seeds. This product is somewhat less soluble, both in water and in dilute alcohol, than either arecaine or arecoline, and can be separated from arecaidine by treatment with methyl alcohol and hydrochloric acid, being unaffected by these reagents. It forms small glittering crystals, which melt with decomposition at 271—272° C. These are readily soluble in water and in dilute alcohol, insoluble in strong alcohol and in ether, chloroform, and benzene. The solutions are neutral. Analysis points to the formula $C_6H_9NO_2$ for the new alkaloid. With acids guvacine forms crystalline salts which have an acid reaction, and which behave similarly to the free base with the above-mentioned solvents. The hydrochloride, sulphate, gold and platinum double chlorides are described. The platinum salt has the formula $(C_6H_9NO_2 \cdot HCl)_2 \cdot PtCl_4 \cdot 4H_2O$; it loses its water of crystallisation at 110°, and darkens on heating to 210°, melting a few degrees higher. The gold double chloride contains no water of crystallisation. It melts at 194—195° C. The bases isolated up to the present by the author from the areca-nut are the following:—

Choline.....	$C_5H_{13}NO_2$
Guvacine.....	$C_6H_9NO_2$
Arecaine.....	$C_7H_{11}NO_2 + H_2O$
Arecaidine.....	$C_7H_{11}NO_2 + H_2O$
Arecoline.....	$C_8H_{13}NO_2$

With the exception of choline these bases appear to be closely related one to the other. Full details concerning these bodies will be published in the Archives de Pharmacie. —C. A. K.

Camphrone; a Product of the Action of Dehydrating Agents on Camphor. H. E. Armstrong and F. S. Kipping. Proc. Chem. Soc. 1891—1892, 188—189.

The action of concentrated sulphuric acid on camphor appears to have been first examined by Chautard; it was subsequently studied by Fittig, Schwanert, and Kachler, all of whom agree in stating that under suitable conditions an oily product, having a strong peppermint odour, is formed, isomeric with acetophorone, $C_9H_{14}O$, which consequently has figured in chemical literature under the name *Camphorone*. The various statements regarding the properties of this substance, however, are by no means confirmatory, Fittig stating that it boils at 204°—205 and that it has a relative density of 0.939 at 12°, whereas Schwanert gives 230—235° as its boiling point and 0.9614 at 20° as the relative density.

Armstrong and Miller noticed the presence of a substance having properties similar to those of the product obtained by means of sulphuric acid among the products of the action of zinc chloride on camphor; but attempts which they made to isolate a definite substance from their crude product were unsuccessful.

It appeared probable that, with the aid of the improved methods of treating ketonic compounds now known, it

would be possible to separate the characteristic constituent from the crude oil, and this has proved to be the case.

On treating the fraction boiling at 238° — 242° of the oil prepared by means either of sulphuric acid or of zinc chloride with phenylhydrazine, a mixture of a crystalline hydrazone with dark-coloured, oily products is obtained; the purified hydrazone crystallises in yellowish plates and melts at about 108° . By boiling it in alcoholic solution with ferric chloride and muriatic acid, an oil is obtained which yields a hydrazone identical with that from which it was prepared; on distilling this oil, the thermometer rapidly rises to 245° , the greater part of the liquid passing over at 245° — 247° . On treatment with hydroxylamine, the oil is converted into a hydroxime which crystallises in long prisms melting at 85° — 86° , of which the acetyl derivative melts at 69° — 70° .

Numbers were obtained which agree satisfactorily with the formula $C_{10}H_{12}O$. A more complete study of the compound to place its composition beyond doubt, especially as the formula $C_{10}H_{12}O$ is a very remarkable one, will be made.

PATENTS.

Improvements in the Manufacture of Oxygen. J. C. Lawson, London. Eng. Pat. 15,998, October 9, 1890. 8d.

The object of this invention is to obtain oxygen from the air by means of a continuous process, which consists essentially in passing ozonised air through a compound capable of readily absorbing the oxygen, and of giving it off again when heated in a current of steam. The method of working is to draw air by means of a fan through an ozone generator, which contains a number of plates made of glass or other insulating material. The plates are varnished and coated on their upper sides with perforated tin or other metallic foil. These foils are connected alternately with the terminals of the high potential circuit of an induction current. The air on leaving the ozone generator passes to a retort in which is placed the substance capable of absorbing the oxygen from the air, such as commercial manganate of soda, which may be mixed with oxide of copper. The retort is heated in a suitable furnace and is provided with a pipe and cock for the admission of steam, and also with an exit pipe through which the liberated oxygen can pass through a washer to the gas-holder, a bye-pass being provided for the escape of the nitrogen. The sodium manganate is first treated with steam and the evolved oxygen collected; when no more is evolved the steam is turned off, and the ozonised air led through the hot retort when re-oxidation ensues, the oxygen taken up being again liberated on a second treatment with steam. By employing a suitable arrangement of four retorts the process can be worked continuously.—C. A. K.

A New Product Possessing the same, or nearly the same, Properties as Spirits of Turpentine. T. Drake, Huddersfield. Eng. Pat. 16,916, October 23, 1890. 4d.

Improvements in the Manufacture and Production of Salols and Analogous Compounds. C. Kolbe, Radebeul, Germany. Eng. Pat. 17,221, October 28, 1890. 6d.

In the various methods employed by the patentee for the manufacture and production of salols, it has been found that cinnamic acid can be employed in place of the different acids hitherto used, and that the phenols can be replaced by glycerol (Eng. Pats. 8018 of 1886; 10,260, of 1887; 13 and 169 of 1888; this Journal, 1886, 577; 1887, 561; 1888, 587; 1889, 817). In this manner the following new bodies are produced:—Cinnamates of guaiacol, creosol (*i.e.*, methyl guaiacol), and engelol (*i.e.*, allyl guaiacol); mono-di- and tri-salicylates of glycerol; mono-di- and tri-eresotates (ortho, meta, and para) of glycerol and mono-di- and tri-cinnamates of glycerol. These substances form colourless bodies insoluble or only soluble with difficulty in water, but soluble in alcohol, from which solvent they can be recrystallised. They dissolve without decomposition in

cold dilute soda, but are saponified on heating the solution. When cooled considerably below their point of solidification these bodies often remain liquid. Details regarding the methods of preparation of some of the above substances are given. These new salols can be employed as healing agents.—C. A. K.

Production from Mineral Oils of Sulphonic Acids and Sulphones, and the Manufacture of a New Product by Treating Gelatinous Matters with Sulphonic Acid. A. M. Clark, London. From the "Gewerkschaft Messel," Grube Messel, Germany. Eng. Pat. 19,502, November 29, 1890. 6d.

Processes for Obtaining the Two Isomeric Monomethyl-ethers of Proto-catechuic Aldehyde. J. Bertram, Leipzig, Germany. Eng. Pat. 20,264, December 12, 1890. 6d.

THE di-metallic sodium salt of protocatechuic aldehyde when treated with molecular quantities of the halogen compounds of methyl or with the methyl sulphates of the alkalis or alkaline earths, yields the sodium salt of the meta-methyl ether of protocatechuic aldehyde (vanillin), whilst the mono-sodium salt of the aldehyde, when similarly treated, forms the isomeric para-methyl ether (isovanillin). These reactions are represented by the following equations:—

Vanillin.

Isovanillin.

By the action of sodium methylate on mono-acetyl protocatechuic aldehyde vanillin is obtained, whilst from the di-acetyl compound acetyl isovanillin results, from which isovanillin is prepared by isoposition. The quantities required for carrying out the above reactions are given in the specification. The products are purified by distillation in vacuo; vanillin boils at 170° C. and isovanillin at 179° C. under a pressure of 15 mm. (Compare this Journal, 1891, 854.)—C. A. K.

An Improved Process for the Production of Camphor. W. W. Horn, London. From F. de Mare, N. N. M. Saunier, and G. Dambmann, Paris, France. Eng. Pat. 21,294, December 31, 1890. 4d.

THE object of this invention is to take advantage of the oxidising properties of ozone both on terebenthine and camphene. Two methods are used for the oxidation of terebenthine: Firstly, the gum is heated and a current of ozone is caused to pass over it at the very moment of the separation of the terebenthine, camphor being produced, distilled, and condensed in the cold parts of the apparatus; secondly, ozone is caused to act upon the vapour of terebenthine, and the camphor vapour condensed. For the preparation of camphor from camphene, the latter is obtained by treating the monochlorhydrate of terebenthine with an alkaline carbonate at a temperature of 180° C., and distilling. The camphene is then heated in a receiver to 80° C., ozone being meanwhile introduced. The camphor formed is deposited on the sides of the receiver.—E. G. C.

Improvements in the Purification of Chloroform. S. Pitt, Sutton. From "Raoul Pietet & Co.," Berlin, Germany. Eng. Pat. 15,514, September 12, 1891. 8d.

THE purification is effected in a copper cylinder, surrounded by a jacket hermetically sealed at top and bottom and provided with an inlet and outlet pipe. A grating is fixed at the bottom of the cylinder on which any suitable filtering material can be placed, whilst a cock is attached below the grating for running off the contents of the cylinder.

The object of the purification is to remove the various products, such as the tetrachlorides of carbon, with which the chloroform is invariably contaminated, even that obtained from chloral, and is carried out in three stages. First the chloroform in the cylinder is cooled down to 80° C. by allowing ethylchloride, ethylene, protoxide of nitrogen or "Pietet's liquid," to evaporate in the jacketed space outside the cylinder, and filtering the cold liquid mass. Foreign bodies crystallising above this temperature are thus removed, from which the liquid chloroform is filtered off through the above-mentioned grating. The second stage is to solidify the chloroform thus obtained by reducing the temperature of the cylinder to - 82° C., when about two-thirds of it freezes against the sides of the reservoir. The remaining liquid is drained off, and the solid chloroform melted and then run out of the cylinder for the second time. The product thus obtained is finally subjected to distillation at a very low temperature under reduced pressure, the cylinder used in the previous stages of the purification now serving as the receiver. The first and last portions of the distillate are rejected, whilst the intermediate product, amounting to about 80 per cent. of the total, is obtained as chemically pure chloroform.—C. A. K.

Improvements Relating to Carbonic Acid Baths and Tablets for Use therein. E. Sandow, Hamburg, Germany. Eng. Pat. 16,422, September 28, 1891. 4d.

See *under VII.*, page 37.

A New Antipyretic and Antineuralgic Chinolin Derivative, and Process for the Production of the same. A. Bang, Leeds. From G. A. Dahl, Barmen, Germany. Eng. Pat. 17,493, October 14, 1891. 6d.

ORTHO-HYDROXY-QUINOLINE, when boiled with an alcoholic solution of an ethyl haloid ester and sodium hydrate, is converted into ortho-ethoxy-quinoline, as has been shown by Fischer and Renouf (Ber. 17, 759). This product when nitrated is converted into a mixture of mono- and dinitro-compounds, from which the former can be separated owing to its greater solubility in water. The mono-nitro-ethoxy-quinoline yields the corresponding amido-compound on reduction, which latter is converted into a mono-acetyl compound when treated with glacial acetic acid, or when its hydrochloride is boiled with a mixture of sodium acetate and acetic anhydride. The resulting acetyl compound is the new antipyretic and antineuralgic. It forms white needles, which melt at 155° C. They dissolve readily in alcohol, fairly readily in hot water; they possess slightly basic properties, dissolving readily in dilute acids to form salts. Its mineral acid salts are readily decomposed on boiling, and gradually on crystallisation. The constitutional formula for the acetyl-compound is the following:—

Ortho-ethoxy-ana-mono-acetyl-amido-quinoline.

Full details for the preparation of the products concerned are given in the specification.—C. A. K.

XXII.—EXPLOSIVES, MATCHES, Etc.

High Explosives in Warfare. Commander F. M. Barber, U.S.N. J. Franklin Inst. 1891, 131, 117—140.

THE author, while mentioning that all civilised nations are experimenting with and adopting high explosives in place of gunpowder for many military and naval purposes, points out that his subject is hardly practical, as high explosives cannot yet be said to have been regularly used in warfare. The simplest applications of these explosives in warfare are in connexion with torpedoes. While experimenting with different explosives under water Gen. Abbot found that nitroglycerin was 20 per cent. less effective under these circumstances than dynamite No. 1. His idea was that nitroglycerin was too quick in its action, and since water is slightly compressible, a minute fraction of time is required in the development of the full force of the explosive.

Gun-cotton is generally employed in America and Europe for naval purposes, although Russia, Austria, and Italy also use blasting gelatin. Experiments in England have shown that the explosion of 500 lb. of gun-cotton placed 40 ft. below any ship will sink her.

Mines for harbour defence are either buoyant or on the ground. The former contain from 400 to 500 lb. of explosive, the latter from 500 to 1,500 lb., and these are not efficient when the water is over 100 ft. deep.

Torpedoes carry from 75 to 250 lb. of explosive, and those of the automobile variety attain a speed of 25 to 30 knots for 400 yards. The speed of the controllable torpedoes is about 19 knots, and their effective range one mile.

The next application of high explosives is as bursting charges for shells. After discussing the various calculations and experiments which have been made to estimate the force of the different explosives, the author considers the following a fair rough estimate of the bursting charges of shells:—

Powder.....	1
Gun-cotton and dynamite	6—10
Nitroglycerin.....	13—15
Blasting gelatin.....	15—17

There are two ways of applying explosives in shells. The one, in which a comparatively thick shell is employed, for piercing armour plates, and containing a small quantity of explosive, the other, in which a very large amount of explosive is thrown, contained in a shell made as thin as possible.

In this case the efficiency does not depend on the dispersion of the pieces of shell, but upon the devastating force of the bursting charge itself upon everything within the radius of its explosive effect.

There are, however, great difficulties in the firing of high explosives in shells owing to the liability of the shock of firing to explode the charge in the shell before it leaves the gun or mortar. In Europe these difficulties have been attacked by trying to modify the explosive so that it can be fired with safety from the ordinary powder gun, while in America the high explosive has been taken as it is, and the gun adapted to it. In the pneumatic gun the pressure is low and can never exceed that in the firing reservoir, which is 1,000 lb. per square inch. Hitherto with this gun no accidents have happened while firing the most powerful explosives in their natural state and in quantities over fifty per cent. of the weight of the projectile.

Projectiles weighing 950 lb. and containing 300 lb. of blasting gelatin and 200 lb. of dynamite No. 1, have been thrown nearly one mile and exploded after disappearing under water. It is calculated that this projectile would have sunk any ironclad floating within 47 ft. of where it exploded.

The effect of high explosives upon horizontal armour is very great, but vertical armour has not yet been shattered.

—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Determination of the Specific Gravity of Viscid Substances. J. W. Brühl. Ber. 1891, **24**, 2455—2457.

A PIPETTE containing the viscid substance is inserted into a graduated flask, which being then exhausted by means of a side tube attached for that purpose, becomes charged with the viscid substance as it is sucked from the pipette. This is the arrangement and method adopted by the author (Ber. **24**, 1892), which, he points out, with a 10 cc. flask readily gives results accurate to four places of decimals, and which he considers decidedly preferable for accurate scientific work to Scheibler's arrangement of a pipette closed with two stop-cocks (this Journal, 1891, 657), inasmuch as this apparatus is open to the same objection as the specific gravity bottle supplied with a capillary bored stopper, namely, inconstancy of volume, an error which however would be diminished by using a large pipette with small stop-cocks.—D. A. L.

Vacuum Desiccator with Heating Arrangements. J. W. Brühl. Ber. **24**, 2457—2459.

THE plate which carries the bell-jar is furnished with three openings, one serving the ordinary purpose of exhausting, the other two carrying brass tubes 1 cm. in diameter, about 12 long, and extending 7—8 cm. above the plate, where they are soldered into a circular box about 15 cm. in diameter, and 1 cm. in height, made of copper plate 2 mm. thick, and furnished with several supports soldered inside to prevent its bursting when the bell-jar is exhausted. The tubes are fixed air-tight through the plate by means of brass flanges, caoutchouc stoppers, and screw-nuts. The box serves to support the vessel containing the solution to be evaporated, and can be heated by hot air, water, or steam, while a vessel filled with an absorbent may be placed under the box if required.—D. A. L.

PATENT.

Improvements in or Appertaining to Mercurial Air-pumps. W. P. Thompson, Liverpool. From A. Raps, Berlin, Germany. Eng. Pat. 2969, February 18, 1891. 8d.

THESE improvements, relating to an appliance for automatically actuating mercurial air-pumps, are claimed as consisting, firstly, in the use of a smaller counterweight for the oscillating lever, combined with an adjustable weighted arm. Secondly, in the introduction of an expansion vessel in the pipe leading from the three way cock to the oscillating mercury receptacle.

For further details the specification must be consulted.—B.

INORGANIC CHEMISTRY.—
QUALITATIVE.

A Delicate Test for Alum in Potable Water. Ellen H. Richards. Technology Quarterly, 1891, **4**, 194—195.

THE precipitation of alumina on the addition of alum to natural waters is proportional to the amount of carbonates or bicarbonates present in the water. The precipitation is gradual, and a water which will give a reaction for alum immediately after filtration may give none after 24 hours. Effluents from filters using alum which are originally clear frequently become cloudy on standing from separation of aluminium hydrate. When alum is added to brown surface waters the precipitation of alumina is due to the colouring matters, tannin and other substances.

The author's test is as follows:—"To 25 cc. of the water (concentrated from one liter or more, if necessary) are added a few drops of freshly prepared logwood decoction; any alkali is neutralised, and the colour brightened by the addition of two or three drops of acetic acid. By comparison with standard solutions, the amount of alum present may be determined. One part of alum in 1,000,000

of water can be detected with certainty. In cases of greater dilution, concentration of several litres may be necessary to obtain a decisive test. The logwood chips yield the right colour only after having been treated with boiling water two or three times, and rejecting the successive decoctions. The first portion gives a yellow colour, the third or fourth a deep red."—A. G. B.

Electrolytic Separations. E. F. Smith and F. Muhr. Ber. 1891, **24**, 2175—2181; and Amer. Chem. J. 1891, **13**, 417—422.

THE electrolytic deposition of gold from alkaline aurocyanides is well known, and the author has now demonstrated how this property may be applied to the separation of the precious metal from palladium, platinum, copper, cobalt, nickel, and zinc. Palladium, for example, in solutions containing excess of potassium cyanide, requires a current of $\frac{1}{1000}$ ampère to pass 36 hours before it is deposited, and when gold is also present the latter can be wholly separated in from 12 to 14 hours, and quite free from palladium. Platinum, and also nickel, resemble palladium in their behaviour under similar circumstances, whilst potassium zinc cyanide requires a current of at least 2—3 cc. of electrolytic gas per minute for its decomposition. The conditions of operation and the results are indicated in the following table, which contains some of the author's results:—

Gold Present.	Potassium Cyanide Present.	Dilution.	Current in cc. Electrolytic Gas Per Min.	Palladium or other Metal Present.	Gold Deposited (extremes).
Grms.	Grms.	Cc.		Grms.	Grms.
0.1162	1.5	150	0.8	Palladium. 0.1209	0.1162—3
0.1162	1.5	150	0.3	0.1200	0.1160—56
0.1162	1.5	150	1.0	0.1200	0.1164—58
0.1167	2.5	150	1.0	Platinum. 0.1233	0.1174—61
0.1725	1.5	150	0.8	Copper. 0.1250	0.1725
0.1725	5.0	150	0.8	0.1250	0.1736
0.1725	3.5	150	0.4	0.1250	0.1735—20
0.1792	3.0	150	0.6	Cobalt. 0.15—0.20	0.1789—99
0.1725	2.5	150	0.5	Nickel. 0.1373	0.1724
0.1725	3.0	150	1.0	0.1373	0.1718
0.1167	2.5	150	0.5	0.1373	0.1162—60
0.1792	3.0	150	0.5	Zinc. 0.2000	0.1796
..	0.6	0.2000	0.1798—90

The slight excess of gold observed in the precipitate in many instances is stated not to be due to the presence of the foreign metal. A battery of 6 to 10 Crowfoot cells was used for these experiments, and the electrodes were $1\frac{1}{2}$ in. apart during the electrolysis, which was performed in a platinum dish.

Solutions containing 0.0770 grm. of silver, 0.2433 grm. of platinum, and 2.5 grms. of potassium cyanide per 150 cc. yield their silver free from platinum by the action of a current of a strength of 1 cc. electrolytic gas per minute; a stronger current brings down traces of platinum as well. Cadmium cannot be separated either from platinum or nickel by this mode of treatment. Mercury, on the other hand, is readily separated from either of the latter metals in cyanide solution; for example, by means of current of a strength of 0.2 cc. electrolytic gas per minute all the mercury can be separated from a solution containing 0.1902 grm. mercury, 0.2433 grm. of platinum, and 2.5 grms. of platinum cyanide per 150 cc.—D. A. L.

The Electrolysis of Metallic Phosphates in Acid Solution.

E. F. Smith. J. Franklin Inst. 1891, **13**, 206—209. (See this Journal, 1890, 898—899.)

The author now finds that cadmium can be separated from manganese electrolytically without any particular difficulty. Some of the heavier metals were studied in the same manner as copper and cadmium (*loc. cit.*).

Platinum is deposited very rapidly from its acid phosphate solution by the current, and can be separated from the metals of the third and fourth groups.

Palladium also separates rapidly and completely from a solution containing free phosphoric acid, but efforts to separate palladium from cadmium, zinc, and other metals were fruitless, for though the palladium was always fully precipitated, it was either associated with the other metals or separated in black spongy masses.

Gold.—No difficulty was experienced in the case of gold by itself, but attempts to separate it from cadmium were unsuccessful, though the separation of gold from zinc could be carried out without the least difficulty. The separation of gold from cobalt was also satisfactory.

The electrolysis of zinc, nickel, cobalt and iron phosphates have thus far not yielded encouraging results. Strong currents seem necessary; even then the deposition of the metals is rather slow.—O. H.

The Electrolysis of the Metallic Sulphocyanides. L. K. Frankel. J. Franklin Inst. 1891, **13**, 144—150.

In a previous paper on the above subject by the present author in conjunction with E. F. Smith (this Journal, 1890, 80) the statement was made that manganese when deposited from a solution containing an excess of potassium sulphocyanide separates as a greyish-white deposit on the negative pole, differing in this respect from solutions of the nitrate or the sulphate from which manganese is deposited as oxide. Furthermore, it was stated that nickel, cobalt, iron, and several other metals separate very rapidly from cold sulphocyanide solutions under the influence of a weak current. In the present paper the above experiments have been repeated, and the action of the current has been tried on various other metallic sulphocyanides, but the results have been for the most part of a negative order.

The decomposition of concentrated alkaline sulphocyanide is described, and the production of a lemon-yellow amorphous deposit, which the author finds to be similar and identical with Bunge's "pseudosulphocyanogen" (Ber. **3**, 297), also described by Lidon, and with "Canarin" (perthiocyanogen, or persulphocyanogen), a yellow colouring matter obtained by the action of chlorine or bromine on sulphocyanic acid (see this Journal, 1884, 166—167, 255, and 476).

In dilute sulphocyanide solutions, however, the formation of the lemon-yellow compound takes place in but small quantities and only after the lapse of considerable time, so that if the current be sufficiently weak and the solution sufficiently dilute, no turbidity will take place in the solution. It was anticipated that this behaviour of the

dilute solution could be utilised for the electrolytic deposition of the metals, but the other products of decomposition exerted such an influence on the solution that in but very few cases were quantitative results obtained. Mercury and gold were the only two metals which gave satisfactory results, the other metals, viz., cadmium, palladium, nickel, cobalt, zinc, iron, manganese, lead, antimony, bismuth, and tin, yielding no satisfactory results whatever.—O. H.

ORGANIC CHEMISTRY.—QUALITATIVE.

The Detection of Turkish Geranium Essence in Rose Oil. G. Panajotow. Ber. 1891, **24**, 2700—2701.

THE rose oil which is brought into the market both from South Bulgaria and from Turkey is very often adulterated with Turkish geranium essence (*Indris yaghi*). The adulterant can be detected by means of a solution of rosaniline decolourised by sulphur dioxide (Schiff's reagent). 2—3 drops of Turkish geranium oil, when shaken with 2 cc. of the reagent in the cold, give first a blue-violet and after two hours a fine blue colouration. Rose oil similarly treated gives a red colouration after prolonged standing (24 hours). Even the smallest traces of the geranium oil can be thus detected by the blue colouration formed on shaking the sample of the rose oil with the above reagent, owing to the fact that it forms so much more quickly than the red colouration produced by the pure rose oil. The geranium oil can also be detected by treatment with strong sulphuric acid. Turkish geranium oil dissolves in this acid to form a thick brown-red liquid which, when treated with 95 per cent. alcohol, turns turbid and separates a flocculent yellow precipitate, whilst the solution becomes red, and after standing some time, yellow. Rose oil also forms a brown-red solution when treated with strong sulphuric acid, but this, when treated with alcohol, dissolves to a clear, colourless solution (compare this Journal, 1891, 63 and 269).—C. A. K.

ORGANIC CHEMISTRY.—QUANTITATIVE.

On an Extraction Apparatus for the Determination of Fat in Milk. E. Molinari. Ber. 1891, **24**, 2204—2209.

IN 1888 Schmid devised a method (this Journal, 1888, 395) for the determination of fat in milk in which 10 cc. of the milk were boiled in a graduated tube with 10 cc. of concentrated hydrochloric acid. 30 cc. of ether were then added to the cooled liquid, and after shaking the volume of the upper layer, was read off, an aliquot part taken, evaporated to dryness, and the residue of fat weighed. The chief objections to this method are that a brown colouring matter is formed by the action of the acid on the casein, which interferes with the observation of the line of separation of the liquids, and also that one extraction with ether is not sufficient to remove all the fat. To avoid these difficulties the author has devised the apparatus figured below:—

APPARATUS FOR DETERMINATION OF FAT IN MILK.

In order to use the apparatus, 10 cc. of milk are weighed or measured into A, 10 cc. of hydrochloric acid are added, and the liquid heated to boiling and boiled for 1½ minutes, with occasional shaking. The liquid becomes first rose-coloured and afterwards brown (not black). The liquid is now cooled, 25 cc. of ether are added, and the two well shaken together. The apparatus is now inverted, allowed to stand for 5–6 minutes, when the dark-brown aqueous portion is run into the flask B, the tap being turned, so that the air-opening *a* communicates with B. After separation of the acid liquid, the apparatus is now replaced in its original position and A is removed. 10 cc. of ether are poured into the cap of B and allowed to enter. After shaking, B is inverted and the brown aqueous liquid drawn off. A is now replaced, and the two ether extracts and washings allowed to mix in A and washed twice with water, the aqueous liquid being drawn off as before. Finally, the ether is evaporated in A, and the residual fat weighed.—H. K. T.

The Use of the Centrifugal Machine in Analytical and Microscopical Work. W. Thorner. Chem. Zeit. 1891, 15, 1201–1203.

THE author has applied the principle of centrifugal separation, which has been already successfully used for the determination of fat in milk by means of the “Lactocrite,” to the analysis of flour, butter, and other food products. The machine used is that known as the Victoria hand separator, which permits a speed of 6,000–7,000 revolutions per minute being obtained.

(1.) *Analysis of Flours and Starches.*—One gram. of the substance to be tested was mixed with water, alcohol, or ether in the tube shown in Fig. 1 to within about 2 cm. of

APPARATUS FOR CENTRIFUGAL SEPARATION.

the upper edge, the contents of the tube well shaken until all lumps had been broken up, and rotated for precisely five minutes at a speed of 2,000–2,500 revolutions per minute. The tube illustrated has a capacity of about 15 cc., while its lower, narrower part holds about 3 cc. and is divided into divisions of 0.1 cc., while these again are sub-divided into fifths so that a volume of 0.2 cc. can be read. The following table shows some of the results.

The results given are the mean of several concordant determinations. The figures in the last three columns represent the volume occupied by the 1 gm. of the sample taken expressed in tenths of a cc. It is apparent, on inspection, that water is the most suitable liquid to use, as it gives greater differences with samples of different origin than either alcohol or ether. The large volume occupied by rye flour as compared with flour from wheat, affords a

	Percentage of Water.	Water.	Alcohol.	Ether.
Wheat flour, I.	14.6	14.3	16.6	15.2
Wheat flour, II.		14.5	16.5	15.6
Wheat flour, III.		15.3	16.0	15.0
Rye flour, I.	14.0	30.0	16.4	16.0
Rye flour, II.		30.0	16.0	15.7
Oat flour.	11.9	30.0	17.8	17.0
Barley flour.	12.5	22.0	16.5	14.0
Pea flour.	17.6	22.4	20.6	18.0
Buckwheat flour.	14.8	19.5	15.8	15.5
Rice flour.	13.8	19.8	14.2	13.9
Rice starch.	15.0	12.6	15.8	15.8
Potato starch.	11.1	13.3	11.0	12.0
Mondamin.	14.1	13.6	12.0	12.4

means for the detection of the former when mixed with the latter as an adulterant. How far this is possible is shown by the following table:—

Percentage of Rye Flour.	Volume in Tenths of 1 cc.
0	14.3
10	15.2
20	16.3
30	17.7
40	18.6
50	20.4
60	21.2
70	23.2
80	26.0
90	28.5

The results hitherto recorded were obtained with ordinary air-dried samples; the percentage of water had a certain influence on the results, though its exact amount has not yet been discovered. The remaining figures are, however, obtained from samples dried at 100°–102° C.

	Volume in Tenths of 1 cc.
Wheat flour, I.	15.4
Rye flour, I.	33.0
Oat flour.	30.0
Barley flour.	22.8
Pea flour.	25.3
Buckwheat flour.	22.8
Rice flour.	23.8
Rice starch.	15.0
Potato starch.	16.8
Mondamin.	15.3

The figures given by a mixture of wheat and rye flour similarly dried were not greatly different from those recorded above for air-dried samples.

The weighing of 1 gm. or 2 grms. of the sample may be conveniently avoided by the use of the little measuring

glass shown in Fig. 2, which contains a definite quantity of flour when gently filled and closed by sliding a small glass plate over the top.

The author has applied the method to the determination of mineral additions, such as chalk and barium sulphate. The centrifugal machine can be usefully applied to the preparation of articles to be examined microscopically. For this purpose 5 grms. of flour are heated with 500 grms. of water on a water-bath. 100 cc. of the resulting liquid are treated with 5 cc. of glacial acetic acid, and another 100 cc. with 1 cc. of caustic potash solution (1:2), then heated for ten minutes on the water-bath and rotated for five minutes. The residue of husks, &c. left at the bottom of the tube after rotation lends itself readily to microscopic examination.

(2.) The method above described is applicable to the determination of the watery constituents in butter or margarine. The measurement of the butter for technical purposes is best effected by the little apparatus shown in Fig. 3, which has a capacity of 10 cc. The tube A having been filled with butter, its ends are closed with plates B B and it is, after being wiped, transferred to the tube of the centrifugal machine, which is placed in a water-bath so as to melt the butter and allow it to run out of A into the centrifugal tube. The tube is then rotated at about 2,000 revolutions per minute for two or three minutes. At the end of this time the lower layer, which has separated from the fat, is seen to consist of two portions, the lower being almost clear and generally containing some crystals of salt and other mineral additions that may be present, as well as such organic materials as flour or starch, and the upper consisting mainly of a layer of caseine suspended in water. The relation of these two layers varies considerably, but their sum represents the total amount of butter-milk present.

The author has also attempted to apply the above method to the determination of fatty acids in butter, using a special form of tube with a narrow graduated neck for reading off the volume of the separated fatty acids. The saponification and subsequent separation of the fatty acids are carried out in the same tube. In conjunction with the above method for the examination of butter, the author recommends the use of the refractometer, the form devised by Pulfrich being convenient. By such means, data said to be sufficient for judging the quality of a sample of butter may be obtained in a short space of time.—B. B.

The Determination of Indigotin in Indigo. F. Ulzer. Mittheil. Techn. Gewerbe-Museums, 1891, 178—184.

THE author has examined the various methods in use, or recently proposed (this Journal, 1885, 489, 491; 1887, 455; 1888, 459; 1889, 640; 1891, 488 and 721) for testing indigo, and considers satisfactory those only which aim at effecting a separation of the indigotin in a pure state. Such a method is the following, which to some extent is an improvement upon a method employed in the laboratory of L. Biach:—A solution of sodium stannite is prepared by the addition of sodium hydrate to 10 cc. of a solution of stannous chloride containing 88 grms. of the crystallised salt per litre. About 0.8 gm. of finely-powdered indigo is mixed with this solution and allowed to stand, with occasional agitation, for an hour, to effect the reduction of the indigotin; 15 cc. of hydrogen dioxide solution (10 vols) are added, and the whole allowed to stand for another hour; then the mixture is acidified with dilute sulphuric acid, heated to boiling and filtered through a weighed filter. The precipitate so obtained, after being washed successively with boiling water, dilute potassium hydrate solution, and hot alcohol, is dried at 100° and weighed. It is then ignited, and the weight of the ash deducted from the previous weighing, the difference giving the amount of indigotin present. The treatment with dilute sulphuric acid removes from the indigo indigo-gluten and similar matters, that with potash and alcohol the indifuscin (indigo-brown) and indirubin (indigo-red) respectively. The washing with alcohol must be discontinued when the filtrate, which initially has a brown

or red colour, shows a clear, pale-blue colour. The following results were obtained:—

	Indigotin.		
	I.	II.	III.
Indigotin (prepared by Fritsche's method).	Per Cent. 97.85	Per Cent. 97.80	Per Cent. ..
Commercial indigo (inferior quality)	44.19	43.91	44.50
Bengal indigo	75.91	75.40	74.81
Tirhoot indigo	57.92
Benares indigo.....	54.39
Indigo (manufactured by ammonia process).	30.05

In a series of experiments made with a view to dispensing, if possible, with the dissolution of the reduced indigo, finely-powdered indigo was treated directly with hot alcoholic potash, then with dilute hydrochloric acid and finally with water. The results obtained, however, were in all cases much too low, the indigotin being apparently acted upon by alcoholic potash. Simultaneous treatment of the indigo with alcohol and alkali being, therefore, unfeasible, recourse was had to Berzelius' method of purification:—A mixture of 0.6 gm. of powdered indigo and 50 cc. of a 5 per cent. solution of sodium hydrate was heated to the boil, cooled, diluted, and filtered through a weighed filter-paper, and the residue washed with boiling water, dilute hydrochloric acid (1:10), and finally with alcohol, then weighed and ignited. In this manner the following results were obtained:—

	Indigotin.		
	I.	II.	III. = First described Method.
Indigotin.....	Per Cent. 98.58	Per Cent. ..	Per Cent. 97.85
Commercial indigo (superior quality).	66.87	66.21	64.35
Commercial indigo (inferior quality).	15.12	44.22	42.01

As it is improbable that any considerable over-reduction of the indigotin takes place in the first-described method of analysis, the author concludes that the last method yields results 2—2.5 per cent. too high. Should further experience prove that this relationship is constant, the latter method would be preferable by reason of its greater rapidity, the results obtained being corrected to the extent mentioned. A correction must also be made for the loss of weight sustained by the filter-paper used for collecting the indigotin, this loss amounting to approximately 1 per cent. of the weight of the dry paper.—E. Metallic Hydrosulphides. S. E. Linder and H. Picton. Proc. Chem. Soc. 1891—1892, 176.

THE authors have investigated the sulphides of copper, mercury, arsenic, antimony, cadmium, zinc, bismuth, silver, indium, and gold. With the single exception of bismuth, all these metals form hydrosulphides of a more or less complicated character, which, in most cases, undergo molecular condensation with elimination of sulphuretted hydrogen when submitted to the action of acids. Taking copper as a type, on treatment with sulphuretted hydrogen, copper hydrate forms a solution of the hydrosulphide $7\text{CuS} \cdot 11\text{H}_2\text{S}$. Acetic acid, in presence of excess of sulphuretted hydrogen, promotes molecular condensation, a product being formed which has approximately the composition $9\text{CuS} \cdot 11\text{H}_2\text{S}$; while acetic acid, in absence of sulphuretted hydrogen, promotes the formation of a product approximately represented by the formula $22\text{CuS} \cdot 11\text{H}_2\text{S}$. Hydrochloric acid produces still further condensation. Mercuric sulphide forms products approximately represented by the formulae $31\text{HgS} \cdot 11\text{H}_2\text{S}$; $62\text{HgS} \cdot 11\text{H}_2\text{S}$. The latter formula represents the precipitate formed in presence of acid, and is a remarkably stable substance. Zinc sulphide solution obtained from the hydrate contains about 14 per cent. excess of sulphur as sulphuretted hydrogen; in presence of acetic acid, a product represented approximately by the formula $12\text{ZnS} \cdot 11\text{H}_2\text{S}$ is formed.

The authors regard their results as evidence tending to support the conclusions that the metallic sulphides are in most cases polymerides of very high molecular weight.

The Physical Constitution of some Sulphide Solutions. H. Picton. Proc. Chem. Soc. 1891—1892, 176—177.

THE author has specially examined the solutions of mercuric, antimonious and arsenious sulphides. In each case the whole of the dissolved sulphide is found to be present in the form of very finely-divided particles. Arsenious sulphide is found capable of existing in "solution" in three distinct types of sub-division. The following examples illustrate the main characteristics of sulphide "solutions":—

Mercuric sulphide.—Particles are visible under the microscope (1,000 diameters); not diffusible even in absence of a membrane.

Arsenious sulphide (α).—Particles are just visible.

Antimonious sulphide.—Particles are not visible, and it is not diffusible, but particles are detected by their power of scattering light, the scattered light being polarised.

Arsenious sulphide (β).—Not diffusible; the particles scatter and polarise light.

Arsenious sulphide (γ).—Diffusible in the absence of a membrane; particles are shown to exist by optical behaviour.

The solutions examined exhibit a series passing from those in which the particles of the solid are visible to those in which the particles simulate the phenomena of liquid diffusion, and, although not visible to the eye, are detected by their power of scattering light.

Solution and Pseudo-Solution. Part I. H. Picton and S. E. Linder. Proc. Chem. Soc. 1891—1892, 177.

THE authors advance what they regard as a good *prima facie* case for the belief that there is a continuous series of grades of solution passing without break from suspension to crystallisable solution. They hold that in the lowest grades of solution a certain loose attraction exists between the particles and the molecules of the solvent. This conclusion they support with experimental evidence gathered from their own work and from other sources. They regard the very finely-divided particles in the lower grades of solution (colloid solution) as large molecular aggregates retaining many of their molecular properties. They consider that in passing up through the different grades of solution, these aggregates on the whole become smaller and the forces by which they are held in solution become more definitely those of chemical attraction. They describe a new property, which seems to hold for a large range of solutions, extending from suspension to crystallisable solution. This property consists in the repulsion of the dissolved substance, as a whole, from one of the electrodes of a battery immersed in the solution. Thus, in the case of colloidal arsenic sulphide, the sulphide aggregates are repelled from the negative electrode. They are also repelled, but much less strongly, from the positive electrode. In the case of the crystallisable colouring matter Magdala red in absolute alcohol, an exactly similar phenomenon is observed, but the repulsion is this time from the positive electrode, and there is no perceptible repulsion from the negative electrode at all. The property is of much interest in itself, but also as exhibiting similarities between the different grades of solution.

In discussion, Mr. Page suggested that observations on the nature of solutions, such as those described by the authors, might with great facility be carried out in capillary tubes under the microscope. Mr. Walenn said that in working with electro-coppering solutions containing resin in suspension he had had occasion to notice a clearing of the liquid at the anode, such as had been referred to. Professor Ramsay said that the problem of Brownian motion, or pedesis, had engaged his attention since 1878, when he published a paper in the "Proceedings of the Geological Society" bearing on the settling of mud in salt water. The problem attacked by Messrs. Linder and Picton was one in which he thought pedesis played an all-important part, as the small particles, the existence of which had been proved by their power of polarising light, were in exceedingly rapid motion. The authors had shown that there is a regular transition from visible particles to particles or molecules such as those of oxyhaemoglobin. It must, therefore, be concluded that such exceedingly small particles are also in rapid motion; and the smaller the particle the more rapid the motion. Pedesis had not received, as yet, any satisfactory explanation; the only fact which appeared to throw any light on its nature was that the addition of a salt to the solvent, rendering it an electrolyte, hindered pedesis, and finally caused coagulation and settling. The discovery of the true nature of pedesis would in all probability be the key to the problem of the nature of solution. Mr. Warrington pointed out that the coagulation of clay by salts had been studied by Schloesing (Chimie Agricole, p. 62; Frey's Encyclopédie, tome X) and W. Skey (Chem. News). Mr. Herbert Jackson said that the phenomena discovered by the authors were similar to those observed in the case of the liquids produced during the washing of many precipitates, such, for instance, as lead hydrate or silver nitroprusside, which refuse to settle completely as soon as the liquid in which they are diffused becomes approximately pure water, or which show a tendency to come through the paper when washed on a filter. Such precipitates can be made to furnish turbid liquids in which the particles are so fine that they will not settle for many months, although, as is well known, the addition of a drop or two of a saline solution, e.g., sodium acetate or potassium nitrate, will cause rapid deposition of the solid.

These opalescent liquids give the results described and shown by the authors when examined at right angles to a narrow beam of strong light.

He had found in the case of lead hydrate that the microscope revealed moving particles with an average diameter of $\frac{1}{300000}$ of an in. Some, in the case of silver nitroprusside, were less than $\frac{1}{700000}$ of an in.

It is quite clear that it is impossible to call a liquid homogeneous because the microscope fails to show structure. All that can be said is that the particles in water, if not visible with lenses of the greatest possible angle for water, are probably not much greater than the $\frac{1}{300000}$ of an inch in diameter. Of course it must be understood that changes in the limits will be observed when the refractive index of the particles differs very greatly from that of the fluid in which they are diffused, as is the case with As_2S_3 in water. It seems probable, therefore, that the phenomena observed in the cases of As_2S_3 , and others which were mentioned, differ only in degree, and not in kind, from those in the cases of Sb_2S_3 , and similar bodies, and from the opalescent liquids obtained in washing many precipitates.

New Books.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der Technischen und Industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN, 1890. Zweites Halbjahr. Zweite Hälfte. Berlin, 1892, R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, S.W. Schöneberger str. 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

THE Technological Repertorium closes for the year 1890 in a volume, the pages of which run from 97 to 224. It ends with an Alphabetical Index. The text is embellished with numerous woodcuts, and pages 217 to 223 are filled with a report of New Books which have appeared in the period covered.

The subjects treated are as follows:—Food Stuffs; Paper; Photography; Residuals, Manures, Disinfection, and Sanitation; Soaps; Explosives; Preparation and Purification of Chemicals; Chemical Analysis; Apparatus, Machinery; Electro-technology; Thermo-technology. Appendix. Special Preparations, Adulterants. New Books,

KURZES LEHRBUCH DER ANALYTISCHEN CHEMIE. Dr. W. v. MILLER und Dr. H. von KILLIAN, Professoren an der k. Technischen Hochschule. München. Zweite vermehrte und verbesserte Auflage. Munich: Theodor Ackermann, Königl. Hof. Buchhändler, 1891. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume bound in the usual paper cover. It contains Title Page, preface to the second edition, Table of Contents, Table of Abbreviations, Table of Atomic Weights, and 598 pages of subject-matter, followed by two tables, one of the Tension of Aqueous Vapour and the other of the Density of Gases. The work is concluded by an Alphabetical Index. Ninety-six woodcut illustrations are contained in the text.

The division of the matter is somewhat novel, though undeniably very effective. It is as follows:—GENERAL METHODS. Qualitative and Quantitative Analysis. Drying of Solid Substances. Weighing of the Substance for Analysis. Solution of Solid Substances. I. Gravimetric Analysis. II. Volumetric Analysis. III. Gas Analysis. I. PART.—THE METALS. First Group: The Alkalies. Second Group: The Alkaline Earths. Third Group, Fourth Group. Fifth Group. II. PART.—THE NON-

METALS. Phosphorus. Nitrogen. Sulphur. Silicon. Boron. Chlorine. Bromine. Iodine. Fluorine. Carbon. Elementary Analysis of Organic Bodies. Analysis of Smoke, Heating, Illuminating, and other Gases. Estimation of Water in Solid Bodies. Spectrum Analysis. The last page of the book contains a chromo-lithograph of the Solar Spectrum. The price of the work is 10s.

ANALYSE DER FETTE UND WACHSARTEN. VON DR. RUDOLF BENEDIKT, Professor an der k. k. Technischen Hochschule in Wien. Zweite Auflage. Berlin: Verlag von Julius Springer, 1892. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS work now runs into a second edition, and consists of an 8vo. volume strongly bound in cloth. It commences with a Preface, and this is succeeded by a Table of Contents. The text covers 460 pages, and concludes with an Alphabetical Index. Thirty-two well executed wood engravings illustrate descriptions of apparatus, &c., given, and the general mode of treatment of the subject may be gathered from the following excerpt of the sub-divisions of the work:—I. Constituents of the Fats and Waxes. A. Acids. B. Alcohols. II. Physical and Chemical Properties of the Fats and Waxes. 1. Fats. 2. Waxes. 3. Behaviour of the Fats during Saponification. III. Estimation of the Substances not Fats, in Mixtures of Fats, and Preparation of the Substance for Analysis. IV. Methods for Determining the Physical Properties of the Fats. V. Elementary Analysis of the Fats. VI. Quantitative Scientific Investigation of a Fat of unknown Origin. VII. General Methods for Determining the Quantitative Composition of Fats and Fatty Mixtures. A. Quantitative Reactions. B. Quantitative Estimation of Single Constituents of the Fats. VIII. Recognition and Quantitative Estimation of such foreign Substances as are contained dissolved in the Fatty Substance, or melted up with it. A. Estimation of Unsaponifiable Substances. B. Detection of small quantities of Fats in Mineral Oils. C. Investigation of the Unsaponifiable Constituents. D. Detection and Estimation of Resins and Colophony in Fat. IX. Investigation of Materials and Products of the Fat Industry. A. Candles. B. Soaps. C. Turkey-red Oil. D. Lubricating Oils, &c. 1. Glycerin. X. Investigation of Oils. XI. Investigation of Solid Fats and Waxes. XII. Description of Individual Fats and Waxes. XIII. Examples. The price of the work is 9s.

EXPLOSIVES AND ORDNANCE MATERIAL, considered with reference to some recent experiments with Emmensite, Gelbite, and Aluminium Bronze. By STEPHEN H. EMMENS, Member of the U.S. Naval Institute, of the Society of Chemical Industry, &c. Reprinted from the Proc. U.S. Naval Institute, Vol. XVII., No. 3. Baltimore Press of Isaac Friedland Co. 1891.

THIS is a treatise reprinted from the Proceedings of the U.S. Naval Institute, and is handsomely bound in cloth, forming a volume of large 8vo. size. The pages, numbering 91, are adorned with 11 well-executed photo-lithographic plates. The treatment of the subjects may be gathered from the following sub-division of the text:—Chap. I. The Ballistic Theory of Explosives. II. The Ballistic Theory of Explosion Stress. III. The Comparison of Explosives. IV. Some Remarks upon the Foregoing Tables, and upon the Humanity of Text-books. V. Emmensite. VI. Gelbite. VII. Aluminium Bronze and Ferro-Nickel. The work closes with an ADDENDUM giving some additional results acquired after the preceding matter had been written.

A TEXT-BOOK ON THE SCIENCE OF BREWING. By EDWARD RALPH MORITZ, Consulting Chemist to the Country Brewers' Society, and GEORGE HARRIS MORRIS, Ph.D., F.C.S., F.I.C. Based on a Course of Six Lectures delivered by E. R. Moritz at the Finsbury Technical College of the City and Guilds of London Institute. London: E. and F. N. Spon, 125, Strand. New York: 12, Cortlandt Street. 1891.

LARGE 8vo. volume bound in cloth, with Preface, Introduction, Table of Contents, List of Plates, 514 pages of subject matter, illustrated by 13 well-executed wood engravings and 10 excellent plates exhibiting Microscopic Images. The matter is arranged and sub-divided as follows:—SECTION I. MATERIALS. Chap. I. Brewing Waters. II. Barley and Malt. III. Malt Substitutes. IV. Hops. SECTION II. PROCESSES. Chap. V. Mashing and Sparging. VI. The Boiling of the Wort. VII. Fermentation. VIII. The Racking and Storage of Beer. SECTION III. Chap. IX. The Analysis of Water. X. The Analysis of Malt and Wort. XI. The Analysis of Sugars and Hops. XII. The Analysis of Beer. APPENDIX. Preparation of Standard Solutions. The price of the work is 21s.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade and other Journals.)

RUSSIA.

Customs Decisions.

Note.—Pound = 36 lb. avoirdupois. Rouble = 100 copecks = 3s. 2d.

The following decisions affecting the classification of articles in the Russian Customs tariff have recently been given by the Russian Customs authorities:—

Bones treated with muriatic acid and forming a raw cartilaginous mass (osseine) under section 43, point 2 of tariff.—Duty, 1 rouble 20 cop. gold per pound.

An antimonial preparation representing a raw and an unpurified oxide of antimony under section 92, point 1.—Duty, 20 cops. gold per pound.

Manufactures of Britannia metal not gilt or silvered, even though with stamped ornamentation in relief, under section 149, point 1 (duty, 4 roubles and 80 cops. gold per pound); and the same manufactures with cast or engraved ornamentation in relief, under point 2 of the same section.—Duty, 16 r. gold per pound.

Zinc in rods, under section 147, point 1.—Duty, 50 cops. gold per pound.

Manufacture of copper and copper alloys not gilt or silvered, with cast ornamentation in relief, even though these ornaments form the lids, handles, feet, &c., of these goods, under section 149, point 2.—Duty, 16 r. gold per pound.

Coal tar under section 83, point 3.—Duty, 20 cops. gold per pound.

SWEDEN.

Oleomargarine is henceforward to be treated as butter. Lead wire is freed. At present it pays 1d. per kilo.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220.4 lb. avoirdupois. Franc = 9 $\frac{1}{10}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of November last:—

"Benzolina" (a liquid for removing stains, benzole with the addition of a little ether).—Category 9. Duty, 10 francs per quintal. "Benzolina" is also liable to a monopoly tax (*finance de monopole*) of 3 francs 50 cents. per quintal gross weight.

Manufactures of aluminium.—Category 143. Duty, 16 francs per quintal.

Sulphurous acid, compressed, in tank waggons, is classified at the rate of 2 francs per quintal, according to the net weight, increased by a tare of 30 per cent. of this net weight.

ITALY.

Changes in Customs Duties and Regulations.

Note. — Quintal = 220.4 lb. avoirdupois. Kilog. = 2.204 lb. avoirdupois. Hectolitre = 22 Imp. gallons. Franc = 9 $\frac{1}{10}$ d.

Communications, dated the 8th and 31st December last, have been received from the Foreign Office, transmitting a copy and translation of an Italian decree dated the 22nd November last relative to changes in the Italian Customs duties and regulations, and also copies and translation of a later decree of the 24th December affirming and modifying the stipulations of the same. The various changes introduced by these two decrees are as follows:—

Modifications in Internal Taxes on Manufactures as effected by the Decree of the 22nd November.—Art. 1. The internal tax on the manufacture of sugar is fixed at 63.15 francs for each quintal of sugar of the first class, and 55.95 francs for each quintal of sugar of the second class.

Art. 2. The internal tax on the manufacture of spirits, and the surtax on the importation of spirits from abroad, are fixed at a scale of 140 frs. for each hectolitre of pure alcohol of the temperature of 15.56° measured by centesimal thermometer.

Art. 3. This article is suppressed by the later decree.

Art. 4. The following products which have an alcoholic basis, when imported, are liable to a surtax at the following scale:—

No. in Tariff.	
5	Ether and chloroform, 3.40 frs. per kilo. of ether or chloroform, without abatement for the weight of the actual receiver.
8	Spirituous essences of rum, cognac, or others containing spirit, 0.86 fr. per kilo., without abatement for the weight of the vessel containing the essence.
66	Perfumes containing alcohol, 100.00 frs. per quintal, without abatement for weight of vessel containing.
73	Spirit varnish, 95.00 frs. per quintal at net legal weight.

Art. 5. The tax on the manufacture of beer is fixed at 1.20 frs. for each degree of strength measured with the centesimal saccharometer at a temperature of 17.50° C. for every hectolitre of beer.

In paying this tax the maximum limit of saccharometric degrees is fixed at 16 and the minimum at 10.

(Details follow as to method of test.)

Art. 6. The surtax on beer imported from abroad is fixed at 19.20 frs. per hectolitre, with a facultative reserve to the importer of paying at the scale of its saccharometric or alcoholic degrees if effectually ascertained.

Art. 2 of the decree of the 24th December provides that the tax referred to in Art. 2 of the aforesaid decree is understood to refer only to those who receive goods direct from the place of their origin (*ai soli recipienti d'origine*).

Arts. 3 to 6, inclusive, refer to distilling.

Art. 7. In the case of beer exported to foreign countries, the excise paid in the kingdom shall be restored at the rate of 12 lire (about 10s.) per hectolitre.

Art. 8. Barley intended for the manufacture of beer is allowed a free entry under the conditions established by Royal decree.

Art. 9. Glucose exported to foreign countries is granted a relief from taxation of 90 per cent. by means of a corresponding subtraction from the certified amount manufactured (*accertamenti di fabbrica*).

Art. 10. The amount of the tax on the fabrication of spirit used in the manufacture of vinegar (*aceto*) is fixed at the rate of 70 lire per hectolitre of pure alcohol.

Art. 11. The temporary import of sugar destined for use in the production of sweets (*canditi*) for export is permitted without consulting the Superior Council of Commerce, according to the forms and methods which shall be ordained by Royal decree.

NEW CUSTOMS TARIFF OF MEXICO.

(See *Board of Trade Journal* for January, p. 55 seq.)

TARIFF ON PETROLEUM IN FRANCE.

Report by C. Lavollée for the Committee of Commerce. Bull. de la Société d'Encouragement pour l'Industrie Nationale, 1891, 6, 277—284.

This report compares the duties levied on petroleum oils imported into France, with the tariffs in existence in other European countries, and also gives a history of the origin of the various duties imposed since 1864. The main object of the report is to show the necessity of reducing the protective rates on this import. The author refers to a paper read before the Society on 8th February 1889 by Mr. Besnard relating to the state of perfection to which the manufacture of mineral oil lamps had then been brought, and to the advantages that at that time would have followed a decrease in the Customs dues. M. Rousselle in April 1890 brought to the notice of the Society the small quantity of mineral oil used in the country, and solicited an investigation on this matter by the Committee of Commerce. In accordance with this suggestion a report was drawn up supplementary to the communication of M. Besnard.

The first duty levied on petroleum dates from 4th June 1864, crude petroleum being admitted free and refined oil at 3 francs per 100 kilos. The consumption of oil steadily increased till the eventful year 1871. The use of mineral oil by incendiaries produced an unfavourable impression on this import at that time, and at a sitting of the National Assembly on 29th May 1871 a statute was passed "forbidding the sale or storage of petroleum (or any other mineral oil) without the district police prefect's permission. The penalties for breaking this law were very stringent (fines varying from 16—1,000 frs., and imprisonment from one month to two years). In July in the same year, however, crude oil was admitted at a duty of 20 frs., and refined oil at 32 frs. per 100 kilos. respectively. This tariff was augmented in 1873 to 30 and 37 frs. on the crude and refined oils. In 1881 the duties were altered to 18 frs. on crude and 25 frs. on refined oil per 100 kilos. The Government at present (June 1891) proposes a tax of 18 and 24 frs. for crude and refined oils respectively, the Commission suggesting 1 fr. less for the refined oil. The tariff in 1871 was a measure of social defence, and has become little by little a protective duty for the benefit of the refining industry. The refiners state a high protective tariff is necessary to maintain their industry, their opponents declaring, however, that their industry is very flourishing, and that favour accorded to refiners, who are few in number and employ few hands, prejudices other commerce. From American statistics we find a great excess of petroleum imported by us is crude, a different feature in comparison with other countries. The following figures speak for themselves.

OIL EXPORTED FROM NORTH AMERICA, 1888-89.

	Crude Oil.	Refined Oil.
	Gallons.	Gallons.
France	53,955,708	2,602,061
Germany	3,064,421	138,518,352
England	8,634	58,763,730
Belgium	38,000,000
Holland	41,000,000

Now it seems a strange thing to induce such an extensively industrious country as North America to export a natural earthy product in a crude state when economy in transit and manipulation would be made by exporting the refined oil.

It is stated that lighter dues levied on the mineral oils would very nearly ruin the vegetable oil trades, the colza oil industry, being the one of most importance, supplying 70 per cent. of the total bulk to these oils: the colza oil produced in France during 1887 being valued at 32,000,000 francs. The quantity of oil is annually decreasing in production, owing, firstly, to extension of other lighting agencies, and, secondly, to the farmers preferring to grow other crops, principally beetroot. This diminution of colza production is also noticed in Belgium and Germany.

The receipts resulting in the mineral oil tariff are perhaps the most important question. In 1871 revenue was 5,000,000 francs; in 1880 (on 63 million kilos.) 21,000,000 francs; in 1888 (on 155 million kilos.) was 32,000,000 francs.

The French consumption has enormously increased during the last 10 years, and the Parisian consumption has multiplied three-fold in the last 10 years, notwithstanding the double duty of Customs and city fees. It is natural that a reduction in tariff must affect the receipts, but it is not more certain that the deficit will be almost immediately supplied by the augmented consumption.

As an example of comparative consumption Belgium uses four times the quantity of oil proportionally to France. In Belgium and England neither crude or refined oils pay duty. In Holland equivalent to 1.17 francs per 100 kilos.; Switzerland, equivalent to 1.25 francs per 100 kilos.; Italy, equivalent to 4.00 francs per 100 kilos.; Germany, equivalent to 7.50 francs per 100 kilos.

If these tariffs are compared with the French scale of duties, the excessive amount of the latter can easily be seen. A strong point of argument in favour of lowering the mineral oil tax is in the fact that a tax is, as a rule, in some measure proportionate to the value of the goods taxed. Now, taking the tax of 18 francs imposed on crude petroleum in 1881, the price of the oil has so much decreased that at the present time the duty is about 120 per cent. of the value of the product. To be just and equitable all taxes ought to be calculated in moderate proportion to the value of the material taxed. It appears very necessary to reduce these excessive rates at once; a very large number of consumers would be benefited, and an impetus given to the trade now that lamps and better rectification of the oils has largely increased the value of these oils as illuminants. The extending uses of these oils for petroleum engines and other devices render the taxation on this article a serious and shortsighted policy which the Committee of Commerce strongly wish to see altered.—E. F. H.

GENERAL TRADE NOTES.

COCAINE IN INDIA.

An inquiry was some time ago instituted through the Secretary of State by Dr. McNamara, Examiner of Medical Stores, Madras, if the hydrochlorate of cocaine, which in England costs 12l. per pound, could not be more economi-

cally manufactured either at the Government opium agencies or at one of the quinine factories in India. The Allahabad *Pioneer Mail* says that the matter was considered, and it was found that there ought to be no difficulty in extracting the alkaloid in a laboratory such as that possessed by the Medical Stores Department, Madras. In a reference, however, to the surgeon-general it was found that the total annual consumption of the drug was only $4\frac{1}{2}$ lb., and so it was decided that, for the present at least, it would not be worth while making it. The *Erythroxylon coca* has now been cultivated for many years in several parts of the Presidency. It grows like a weed, and the yield of cocaine from the leaves is fully equal to that obtained from the American shrub. Should there, therefore, be at any time a larger demand for this alkaloid, there would be no difficulty in obtaining a very large amount of the leaves, but it is doubtful if, with the prices now ruling in the market, the cultivation of the plant in any large quantities would pay the planter.

HUNGARIAN INDUSTRY.

Industry in Hungary made rapid strides in 1890. According to the *Journal de la Chambre de Commerce de Constantinople* a number of the old factories have been

re-organised in accordance with all the exigencies of modern science, while a large number of new establishments have sprung up throughout the country. The capital sunk for this purpose was nearly 2,500,000*l.* (taking the Austrian florin as equivalent to 2*s.*), whilst the number of factories amounted to 1,132, with those in Croatia and Slavonia to 1,249, and with the alcohol factories to 1,516. The Hungarian Minister of Commerce has ordered a new census of all the industrial establishments in the country, inclusive of Transylvania; this shows that at the present time there are in Hungary 1,871 factories.

Among the new industrial establishments the following are worth mention: the gelatin factory of Pilich and Co. at Szeged; the industrial company for linen and hemp products at Ujszeged; the tallow factory of Redlich and Sons at Kobanya; the condensed carbonic acid factory of Baron Gabriel Apor at Kukullo; the match factory of Michel Salzer at Kova-zua; a large cement factory of M. Lazare Blau at Hunyad; the cotton spinnery of William Low at Segesvar; lastly, the French Mercury Mining Company of Zalatisa, with a capital of 80,000*l.*, the director of which is M. Labreux, a French engineer.

Several other factories and a large number of steam mills have been established within the last few months in different parts of Hungary and Transylvania.

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

PRODUCTION OF BEET SUGAR IN RUSSIA IN 1888—89.

Bull. Soc. d'Encouragement l'industrie Nationale, 1891, 6, 166—171.

This article refers to the sudden rise in the output of sugar in Russia during the season 1888—89, as shown in the following figures :—

Season.	Number of Works open.	Quantities Produced.
		Pounds.
1881—82	235	15,336,714
1882—83	237	17,537,890
1883—84	244	18,879,739
1884—85	245	20,958,120
1885—86	241	20,039,594
1886—87	229	25,949,631
1887—88	218	23,749,028
1888—89	224	28,333,027

(1 pound = 16·381 kilos.)

The sudden rise in output in 1888—89 is connected with the increase of the area under beetroot cultivation, an increase of not less than 6 per cent. of the three regions (South-West and Central Governments, and Poland), in which beetroot is grown, the increase is greatest, 27 per cent., in the South-West district, and least, 4 per cent., in Poland.

Of the 220 works in operation during 1888—89, 186, or more than four-fifths, were for raw sugar.

Of the 220 works, only 8 employed hydrauic presses, the other 212 using the diffusion method.

The number of works in which the output was above 100,000 pounds, was 101 in 1887—88 and 135 in 1888—89, the principal increase being in the South-Western district.

—V. C.

MINERALS IN PERSIA.

Chem. Zeit. 1891, 15, 1240—1241.

Up till now the following ores have been found in paying quantities: Iron, copper, lead, antimony, manganese, nickel, cobalt; also coal, asbestos, borax, and cinnabar. There also exists petroleum springs. Copper and lead ores have been worked by the natives for many ages, but it seems that they chiefly smelted the more readily reducible ores, such as red copper ore, malachite, azurite, white or yellow lead ore, and galena. Ores rich in sulphur, such as black or grey copper ore, were either not used at all, or mixed in small quantities with the other minerals. Near old smelting works may be seen vast accumulations of litharge, which points to the ancient production of silver from argentiferous galenas.—L. de K.

THE RUSSIAN QUICKSILVER MINES.

In addition to the quicksilver mines in operation near Bakhmout, in European Russia, which produce at the present time 20,000 pounds of mercury annually, deposits of mercury have been discovered in the province of Daghestan, in Caucasus, and the mining administration has every reason to believe that private enterprises will be established which will make undertakings of this kind very profitable. The Ministry of Domains has decided to tax Russian mercury, as is done with all other Russian metals. It is proposed to establish taxes of 50 copecks per pound of pure mercury and of 45 copecks per pound of cinnabar made from Russian mercury.—*Chemist and Druggist*.

BOARD OF TRADE NOTICE.

RIVER POLLUTION IN SPAIN. (TENDERS FOR SEWAGE WORKS.)

The municipality of Bilbao are about to invite engineers to submit preliminary plans for a system of sewers to prevent the pollution of the river Nervion. The best four plans will receive premiums varying between 10,000 and 1,000 pesetas. Five months are allowed for the preparation of the plans. Copies of the conditions can be obtained of the secretary of the Ayuntamiento of Bilbao, and a copy can be seen at the Commercial Department of the Foreign Office, London, between the hours of 11 and 5.

ARTICLES OF INTEREST TO TECHNOLOGISTS AND OTHERS.

The following articles in the *Board of Trade Journal* for January will repay perusal:—

"Artificial Butter Legislation in France," p. 22.

"Belgian Coal and Iron Industries," p. 24.

"The Salmon Industry in British Columbia," p. 31.

"Mining Industry of Colombia," p. 68.

"The Production of Aluminium," p. 70.

"Quicksilver Mining in Russia," p. 71.

"Cryolite Production in America," p. 77.

"Anthracite Coal in West Virginia," p. 82.

"Fibre Industries in the Punjab," p. 85.

"The Wealth of Nova Scotia," p. 89.

"Mineral Production of New South Wales," p. 90.

"Mineral Production in Queensland," p. 92.

"The Coal Industry of Natal," p. 95.

POST OFFICE NOTICE.

ALTERATIONS OF BOOK POST RULES.

On and from the 1st January 1892, the following alteration of the Book Post rules came into operation:—

Open Envelopes for Book Packets.

In addition to covers entirely open at the ends, ordinary envelopes left wholly unfastened will be admitted as covers for book packets, whether addressed to places in the United Kingdom or to places abroad.

NICKEL.

THE production of nickel in the United States was considerably smaller in 1891 than in the previous year, owing to the falling off in the output of the famous old Lancaster Gap mine, which was idle for three months of the year. This mine, as is well known, is rapidly approaching exhaustion, and in the future it may be expected to show a constantly diminishing output. Its product in 1891, however, as in previous years, represents practically the entire product of nickel in the United States. The St. Joseph Lead Company, of Boume Terre, Mo., and the Mine La Motte, of St. Francois County, Mo., made their usual out-turn of nickel and cobalt, but the amount is trifling. The ore of these mines is galena in a gangue of magnesian

limestone, with which is associated some iron pyrites carrying a small percentage of nickel and cobalt, and this pyrites is saved as a by-product, being shipped to the American Nickel Works, at Camden, N.J., for reduction.

No work of any consequence was done at the Oregon mines during the year, but some exploration work was done in the Nevada mines. The latter are located at the junction of Bolivia and Cottonwood cañons in Churchill County, about 41 miles east of Lovelock's Station. One of these mines, the London, is owned by the National Nickel Mining Company, of New York and London, which has been working a force of 10 men for the past 12 months and has produced some nickel ore. A small lot of selected ore, perhaps 40 tons, was shipped to England for a test; this is

not included in our statement of the production of nickel in the United States in 1891.

The production of nickel in the United States from 1876 to 1891, both years inclusive, together with the imports into the country and the exports from it, are given in the following table:—

PRODUCTION OF NICKEL IN THE UNITED STATES; ALSO IMPORTS AND EXPORTS.

Year.	Production.			Value of Imports.	Value of Exports.
	Amount.	Average Price.	Value.		
	Lbs.	Dols.	Dols.	Dols.	Dols.
1876	201,367	2.60	523,344	10	203,150
1881	265,668	1.10	292,235	122,120	30,480
1886	182,345	0.60	109,407	141,546	51,323
1888	150,637	0.60	114,382	138,290	39,376
1890	206,332	0.65	136,216	376,279	471
1891	141,841	0.60	86,905

During the past year the consumption of nickel has undergone a large increase, due principally to the growing demand for the metal for use in the manufacture of nickel-steel, the Creusot works, in France, alone having contracted for a large part of the product of the Société du Nickel, while the United States Government purchased the great quantity of 6,500 tons of Canadian matte, containing probably about 20 per cent. nickel. There has also been a natural increase in demand from the nickel-platers, the German silver manufacturers, and other consumers. At the present time, moreover, the prospects seem to be that the consumption of nickel will further increase in 1892. During the past autumn the United States Government made elaborate tests of nickel-steel and other kinds of armour-plate at Indian Head, Md., which resulted in a decisive victory for the nickel steel, and this has now been adopted as the protective material for the new cruisers and battleships. The use of other nickel alloys is constantly growing and a steady expansion in demand may be expected from this source.

The exports of nickel from New Caledonia in 1890, according to a recent consular report, amounted to 3,360 lb., and of nickel ore to about 5,000 metric tons, which, averaging about 8 per cent. nickel, was equivalent to about 882,000 lb. of metallic nickel, representing a total export of 885,360 lb. The production of nickel (in nickel-copper matte) in Canada in 1890 was 1,336,627 lb., that being the first year for which statistics of the Sudbury district were published. The last official statistics of the mining industry of Norway, those of 1889, gave the production of nickel in that country as 149,872 lb.; the output in the preceding year was 145,464 lb., and that of 1890 was probably about the same. The product of Sweden in 1890 was but 17,632 lb., which was a great falling off from the preceding year.—*Engineering and Mining Journal*.

ALUMINIUM.

Aluminium was first made in any quantity in 1855, its value at that time being 90 dols. per lb.; with improvements in the methods of manufacture the price was gradually reduced to 4.86 dols. (11.) in 1887, but the recent development of the industry dates only from 1889, when the Pittsburgh Reduction Company placed aluminium made by the Hall process on the market at 2 dols. per lb. The Pittsburgh Reduction Company commenced operations in November 1888, the Cowles Electric Smelting and Aluminium Company being engaged at that time in the manufacture of aluminium alloys, but is now producing pure aluminium; these were the only companies producing pure aluminium in the United States in 1889, in which year the production amounted to 47,468 lb., valued at 97,335 dols. The total production of aluminium in the world from 1860 to 1889 inclusive is estimated by Mr. R. L. Pickard, Special Agent of the Eleventh Census, at 232,000 lb.

PRODUCTION AND IMPORTS OF ALUMINIUM IN THE UNITED STATES SINCE 1881.

Year.	Production.		Imports.	
	Amount.	Value.	Amount.	Value.

* Partly estimated.

+ Fiscal years.

The principal producers of aluminium in Europe at the present time are the Cowles Syndicate Company, Limited, and the metal Reduction Syndicate, Limited, of England, using the Cowles and Hall processes respectively, and the *Aluminium Industrie Actien Gesellschaft*, of Lauffen-Neuhausen, in Switzerland, which uses the Heroult process. In the United States are the Pittsburgh Reduction Company, with works at Kensington, Pa., and the Cowles Electric Smelting and Aluminium Company, with works at Lockport, N.Y. The United States Aluminium Metal Company, which controls the Heroult patents in the United States, has a plant at Boonton, N.J., which was originally erected for demonstrating this process and has produced some metal, but has not been in regular operation. The Wilson Aluminium Company is now establishing works at Leakesville, N.C., for the application of a process invented by Thos. L. Wilson, and expects to be in operation early in the present year. Works are also being erected at St. Michel, Savoy, France, at which the Minet process will be used.

The production of aluminium and aluminium in alloys in the United States in 1890 was about 95,000 lb. In 1891 there has been a noticeable increase, and the total output for the year may be set down as 163,820 lb. The Cowles works have run steadily throughout the year, but the Pittsburgh works were idle from April to November, during which time the plant was removed from Pittsburgh to Kensington, Pa., this change having been made necessary by the failure of natural gas in Pittsburgh. The new works were put in operation on November 12.—*Ibid*.

BROMINE.

The production of bromine in 1891 was 415,000 lb., divided as follows:—Pennsylvania, 140,000 lb.; Michigan, 45,000 lb.; Ohio, 110,000 lb.; West Virginia, 120,000 lb. The production for the past nine years is shown in the following table:—

PRODUCTION OF BROMINE IN THE UNITED STATES.

States.	1883.	1885.	1887.	1889.	1890.	1891.
	Lb.	Lb.	Lb.	Lb.	Lb.	Lb.
Ohio	194,450	123,000	104,662	150,000	200,600	{ 110,000 120,000
West Virginia	106,650	85,000	16,425			
Pennsylvania	..	60,000	78,000	60,000	70,000	140,000
Michigan....	..	40,000	..	40,000	40,000	45,000
Total....	301,100	310,000	199,087	250,000	310,000	415,000

The output has been for several years and still remain somewhat in excess of consumption.—*Ibid*.

BICHROMATES.

Baltimore is the great centre of the American bichromate manufacture. The firm of Jesse Tyson and Sons for many years had a monopoly of the business. Their process is

a secret one. Within the last few years, however, the salt has been also produced at the Kalion Works, in Philadelphia. Large amounts of bichromate are annually imported in addition to the local product.

SULPHUR.

Brimstone.

The amount of brimstone produced by American mines during the year 1891 was only 1,200 tons, all coming from the Cove Creek mines, 22 miles from Beaver, Utah. About 25 men are now employed at the mines, and about 20 tons a day of brimstone are being shipped. It is not to be expected that Utah or Nevada sulphur can be sold in the Eastern States so long as freight rates remain as at present, yet there is no reason why they should not compete with Japan sulphur products and supply the entire Pacific slope at remunerative prices. The possibility of supplying certain trade centres from outlying mining districts depends almost entirely upon freighting facilities, and Japan sulphur, according to a recent consular report, cannot be carried from San Francisco for less than 16 dols. freight, so that a very small margin is left to the producers after mining and refining costs are discharged. The lowest estimate we have seen for Japan sulphur laid down in California is 26 dols. per ton, whereas there should be no question of the ability of Utah or Nevada mines to supply any reasonable tonnage at a cost not to exceed 17 dols. delivered. The production of brimstone and pyrites in the United States is shown in the following table :—

PRODUCTION OF BRIMSTONE AND PYRITES IN THE UNITED STATES.

Year.	Brimstone.		Pyrites.		Total Value.
	Amount.	Value.	Amount.	Value.	
1882	Short Tons. 600	Dols. 21,000	Short Tons. 13,440	Dols. 72,000	Dols. 93,000
1884	500	12,000	39,200	175,000	187,000
1886	2,500	75,000	61,600	220,000	295,000
1888	60,850	167,658	167,658
1890	109,431	109,431	244,265
1891	1,200	36,000	122,438	122,438	353,280

Progress is noted in operations aimed to open up the great sulphur bed of Louisiana, 230 miles west of New Orleans, on the Southern Pacific Railroad. The sulphur-bearing stratum at this location lies about 500 ft. below the surface, and is shown, by diamond-drill borings, to be of exceptional richness.

The importations of brimstone from Sicily continue on the same generous scale as noted for the past three years, notwithstanding the violent fluctuations in prices over the year as shown by the following table :—

IMPORTS OF SULPHUR INTO THE UNITED STATES FROM 1867.

* Fiscal years ending June 30th, from 1867 to 1887, inclusive; subsequently, calendar years ending December 31st, unless otherwise specified.

† Fiscal years.

This steady consumption is accounted for by the fact that so many new plants for the manufacture of sulphuric acid are being erected in the Southern States and by men who, having no training in the use of pyrites, prefer the good old way of handling brimstone whatever may be the difference in cost.

There is a point in this choice of methods towards an end which the newer class of fertiliser manufacturers do not as yet fully understand, and they will no doubt cling to a use of foreign sulphur until competition of the sharpest kind, with a lowering of prices of all commodities, compels them to make the change or brimstone producers to lower prices.

The older chemical concerns have been working for years in the same rut, and it may be stated as follows :—

COST OF SULPHURIC ACID FROM BRIMSTONE (WORKS BURNING FOUR TONS IN 24 HOURS).

	Dols.
Four tons brimstone, freights, losses in transit and burning, at 30 dols.	120.00
Nitrate of soda, 6 per cent. of sulphur, 53s lb. at 2.50 dols.	13.45
Labour, five men at 1.25 dols. per day	6.25
Coal, 2 tons at 3 dols. per ton	6.00
Superintendent and office cost.	6.00
Wear and tear.	10.00
Total cost for 18 tons 48 B. acid	161.70

Or 1 ton of 48 B. acid costs 8.98 dols.

Now, if this acid were to be sold on the market, it would bring in Boston, New York, Philadelphia, Baltimore, &c., not to exceed 8 dols. net at the factory, and for large quantities even lower prices. These costs and this condition of the market have held for years past, and while circumstances may modify them at times, yet the facts are that no manufacturer of brimstone acid alone has had a remunerative business for many years.

Why, then, do we hear of new plants being erected every year, and the older plants still continuing the use of brimstone? The answer for the fertiliser concern will be an answer for all classes of trade. One ton of 43° B. acid costing 8.98 dols., one ton of ground and dried rock costing 10 dols., labour and power costing 2.02 dols., a total of 21.00 dols., will produce two tons acid phosphate, which is sold to average in commercial fertilisers for 50 dols.; in other words, so long as the ton of 48 B. sulphuric acid can be put into any condition by mixture or change whereby it sells for a large advance on its cost, there is no incentive for the manufacturer to study differences between brimstone and pyrites as available sources for supply of sulphur.

Owing to the enormous prices charged for brimstone, which went up from a normal price of about 20 dols. to 22 dols. a ton to 35 dols., at which it sold this year, there has been a general inquiry for data bearing upon the subject, and during the year past several of the oldest chemical concerns have changed their plants or added new plants to accommodate themselves to manufacture of sulphuric acid from ores.

This has brought in prominence several entirely new sources for the supply of high grade pyrites ores, notably the Spanish and Newfoundland ores, which have been burned at several works along the Atlantic coast with more or less success during the year 1891.

Causes which we have several times referred to, such as the gradual exhaustion of the sulphur-producing territory in Sicily, the lessened percentage of sulphur in the mine products, the increased prices of labour, &c., have combined to lessen the imports for the year 1891, so that an exceptional state of affairs exists at present, viz., brimstone in store commands any price asked from 30 dols. to 40 dols., and "Ex ship to arrive January" brings 29 dols. to 32 dols. per ton.

PYRITES.

We note under this head only such pyrites as are mined for sulphur contents and utilised in manufacture of sulphuric acid, although it is well known that a very large tonnage of pyrites is produced annually as concentrates in dressing gold and silver ores, and that the roasting process necessary to free them from sulphur for the after treatment might be modified or changed to utilise most of the sulphur they contained. We have stated in our annual reports for past years the fact of the general distribution of pyrites over the several sections of the United States, and have published from time to time all the data obtainable to localise values of this now staple commodity. We are constrained to again note the production of pyrites for the year 1891 as limited to two of the Northern States, viz., Massachusetts, 37,320 tons of 2,240 lb., valued at 137,280 dols.; and Virginia, 72,000 tons, valued at 216,000 dols. (these figures being partly estimated). This shows, as compared with last year's reports, that these mining sections have been filling regular orders for established trade, within easy transportation reach, and increasing their production only as required by the natural growth of trade in their own territory. As reported to us the actual sales made by these mines will amount to about 120,000 tons of 2,240 lb., equivalent to 44 per cent. sulphur, or 52,800 tons pure sulphur produced.

IMPORTS OF PYRITES INTO THE UNITED STATES SINCE 1881.

Year.	Quantity.	Average Sulphur Contents.	Year.	Quantity.	Average Sulphur Contents.
	Long Tons.	Per Cent.		Long Tons.	Per Cent.
1881	11,927	35	1889	100,000	43
1883	35,811	34	1890	115,000	43
1885	50,000	38	1891	130,000*	44
1887	60,000	38			

* Estimated.

We estimate the sulphur consumed in the United States during 1891 as follows:—Imports of brimstone, 120,000 tons of 2,240 lb.; imports of pyrites, 130,000 tons (44 per cent. S) 57,200 tons; product of American mines (120,000 tons, with an average of 44 per cent. S), 52,800 tons. We might give details of this consumption, showing how radically the changes are taking place in manufacture of sulphuric acid, and how surely the tendency is to centralise plants in localities near to phosphatic materials—the increase in production of acids being almost entirely for dissolving the hard and river rocks mined in Carolina and Florida. There are 35 acid works in the States south of Maryland, 27 of them built since 1887. It is safe to say that within the coming three years there will be double the acid produced in territory contiguous to the newly-discovered Florida phosphate fields, as it would seem as if the solution of the problem of marketing the enormous tonnage sure to be mined from the hard rock and pebble deposits depends upon a manufacture of these phosphates into acid phosphate.

There exists at present a market for about 100,000 tons of Florida phosphate annually. For acid phosphate there are larger demands, and if prices were lowered to fair manufacturing points these probably can be increased.

With this prospect for Southern industries it is reasonable to suppose we shall have new deposits of pyrites developed in the South pending the opening of the Louisiana sulphur beds. This seems more than likely, as freights into the interior of the Southern States have so far been a bar to entrance of foreign ores, and the local mines will therefore always be able to command a certain trade.

This is shown by taking prevailing prices (which are abnormally high for brimstone) and comparing—

	Dols.
Brimstone, at coast cities, cost	30'00
Freight to interior factories	2'50
	32'50
Foreign pyrites, basis 48 per cent. sulphur, ex-ship 12 c	5'76
Freight to interior cities	2'50
	8'26
Virginia pyrites, at mines	3'50
Freight to interior cities	2'75
	6'25

At points where consumed, the prices of sulphur in each of the above sulphur products would be at present :—

	Dols.
100 units of sulphur in brimstone	31'00
100 units of sulphur in foreign pyrites	18'15
100 units of sulphur in Virginia pyrites	14'50
	— <i>Ibid.</i>

W. T. SARGANT AND SONS' ANNUAL METAL CIRCULAR.

Messrs. W. T. Sargent and Sons report as follows :—

We think the best way to describe the condition of the metal markets during 1891 is to give the following table of prices of some of the chief articles :—

		31st Dec. 1890.	31st Dec. 1891.
		£ s. d.	£ s. d.
Hematite pig iron....	Per ton	2 13 3	2 8 0
Middlesbro' No. 3....	"	2 2 3	1 18 1
Scotch G. M. B.	"	2 6 3	2 7 0
Copper G. M. B.	"	52 15 0	46 15 0
Tin Straits	"	91 0 0	90 10 0
Spelter	"	22 10 0	22 15 0
Lead	"	13 0 0	11 5 0
Quicksilver	Per bottle	9 0 0	7 15 0

The first idea on examination of such a serious and all-round decline in values would be that supplies have exceeded consumption and brought about an increase of stock. The table below effectually disproves this theory.

	31st Dec. 1890.	31st Dec. 1891.
	Tons.	Tons.
Hematite pig iron stock	257,700	191,600
Middlesbro' iron stock	256,262	262,916
Scotch warrant stock	587,652	500,957
Total	1,101,614	955,473
Copper visible supply	65,366	56,544
Tin visible supply	10,930	12,600

That moderate prices should have shrunk 10 to 20 per cent. in face of direct evidence that consumption is distinctly larger than production, proves that some extraordinary power has been at work strong enough for the time to reverse the natural laws of supply and demand.

We are disposed to attribute this unusual and contradictory course of the markets to a combination of the following causes :—

1st. Financial and political disturbances in South America, in conjunction with the McKinlay tariff in the United States, have reduced the volume of metal exports in 1891 to 39,230,009*l.* against 45,251,434*l.* in 1890.

2nd. The deficient harvests in Europe have so raised the value of corn-stuffs that this country's imports for 1891 are valued at 61,571,504*l.* against 53,044,507*l.* in 1890.

3rd. The failure of the United States Act of August 1890 to bring up the value of silver, and the abandonment for the near future of any attempt at a Free Coinage Bill.

Tin.

In its more important aspects, this metal is in striking contrast to the other larger ones. Whilst they show signs of contraction this gives evidence of important expansion. The total production of the year is 57,551 tons against 53,434 tons. The Straits shipments show an increase of 3,987 tons; Dutch tin an increase of 654 tons; and Australian a decrease of 424 tons. English returns are not yet published, but it is admitted that there is no change worth consideration. We leave out of our returns the Bolivian, because we cannot give accurate figures, but although the quantity is small by comparison with other sources it seems to be increasing. The usual reports are in circulation as to new sources of supply in Dakota, Mexico, and California, but beyond the reports of sanguine engineers and interested promoters, there is not a shred of evidence that tin can be produced in any of these countries on terms that can compete with the rich accessible deposits of the Straits, aided by the cheapest labour that exists on the face of the globe. These favourable and unbeatable conditions have last year been greatly assisted by the fall in the price of silver, which raised the dollar price to a very satisfactory level. The Banca mines are being worked more vigorously, and an increased supply of 700 to 1,000 tons will be sold in Holland this year. Therefore the elements of expansion in supply which have been at work in 1891, will apparently be in full force in 1892, and the question for consideration is whether consumption will continue to develop in a similar ratio. According to our calculations, the consumption of 1891 increased by 1,708 tons, but was less than the production by 1,806 tons. The actual stocks in warehouse have remained small, and at the end of last year were only sufficient for about five weeks' supply. Taking the magnitude of the trade into account, this seems very small. As to fluctuations in market value they have been in a smaller compass than for many years. The lowest monthly average was 90*l.* 0*s.* 3*d.*, and the highest 93*l.* 4*s.* The average of the year was 91*l.* 3*s.*, against 94*l.* 3*s.* 6*d.* in 1890, showing a decline of 3*l.* 0*s.* 6*d.* per ton.

TIN PLATES.

The exports both to America and other places show an increase. The total shipments of the entire year give, however, a very inadequate idea of the strain which has been sustained, and, we trust, surmounted. During the first half of the year the American shipments amounted to 263,225 tons, out of the total of 325,145 for the entire year. These were all sold at very satisfactory prices, reaching America before the new duties were imposed. Since then the balance of 61,920 tons has been shipped, but at prices that can barely make both ends meet. It is believed that the surplus shipments to America have been pretty well worked off, and that a good steady trade may be looked for. The establishment of this industry in United States has attained only very small proportions, and as good steel plates with coke finish are obtainable at 12s. 9d. per box f.o.b. Liverpool, we think this country will retain the trade.

COPPER.

The first half of 1891 developed a good demand with firm and rising prices. Notwithstanding considerable arrivals from America, and large offerings of further quantities at prices relatively cheap to G.M.B., the market for the latter was buoyant, and in June touched 56l. 10s. Reports were industriously circulated of strong combinations in existence, or about being formed, for the purpose of sustaining prices at a level in accordance with the improved statistics of the article. But these reports were inaccurate and misleading. For, in fact, the large financiers were steadily unloading their stocks. Under what circumstances and to what extent this has been done is even now a mystery to the general public; but it is suspected that this move was made with a view of depreciating the shares of the Rio Tinto Company and other large concerns, and perhaps coercing the owners of the Anaconda Mine to entertain more modest views as to the value of their property, which was an offer to a syndicate. But whatever may have been the motives or objects of the sellers, the result was to drive prices rapidly down, and in the month of November 44l. 1s. 3d. was accepted for G.M.B. Early in December the sale of the Société's works in France was effected to a new group through the intermediary of the Crédit Industriel, and since then the market has again shown more animation, and, with rather frequent fluctuations, has netted an advance of 30s. per ton, closing to-day at 45l. 13s. 9d. per ton.

The statistics show in Europe a decrease of visible supply during the year of 8,822 tons, to which must be added a very large quantity of privately stored metal. Scarcely anything has been drawn for a long time past by the makers of sulphate of copper, but they have been selling their manufactured article freely, and are now believed to hold very little of either metal or sulphate. The American stock has decreased 10,000 tons. We estimate that the production of 1891 is about 2,000 tons more than that of 1890, but we believe that the current prices, if continued, will both curtail production and stimulate deliveries; and although strong interests have succeeded in depreciating values considerably of late, it is quite within the bounds of probability that equally strong interests may eventually work actively to appreciate them.

IRON.

No metal has experienced more depression than this. The total exports for 1891 have declined to 3,241,035 tons, against 4,001,430 tons in 1890. Although the Argentine Republic shows the most considerable decrease in her takings, yet almost every other customer has also taken less. The home consumption has been fairly good, ship-building in particular having taken increased quantities. The production has been much smaller, each sort showing a diminution; so, notwithstanding the great decrease in exports, our stocks have actually diminished and are extremely small. Prices have been most unremunerative to producers, and furnaces have been dropping out of blast. At the present time the number of Cleveland and hematite furnaces in blast is smaller than for many years, and so soon as demand revives, it would necessitate the establishment of higher prices. The speculative markets for pig metal have been extremely inactive. Owing to the weakness of demand for export, there has been no inducement for dealing on a large scale, and the only important event of the year was a run on Scotch warrants in June and July, when, in consequence of over sales, the dealers had to pay fancy prices to close their accounts. But this being over, the market has lapsed into inactivity, and there is no reason to expect any movement in Scotch warrants, which are quoted nominally at 47s., so long as Middlesbrough No. 3 can be obtained at 38s., as the relative difference is only about 4s. per ton. Whenever the state of trade brings about a rise in Middlesbrough, then the speculative dealings in Scotch will be resumed.

* Estimated.

QUICKSILVER.

Importations have been the smallest recorded for four years. Exports have been large, and exceeded the imports by 1,700 bottles. The actual diminution of stock is this quantity plus the home consumption. During the last 10 years, with only one exception, viz. in 1888, a process of diminution of stock has been going on. The market has had a declining tendency. Opening at 9l. it declined to 7l. 5s. in September, from which it rallied to 7l. 17s. 6d. actual business and 8l. asked. Buyers, being well provided at lower rates, are now holding off; and to-day importers were ready to accept 7l. 10s.

SPELTER.

Consumption and supply seem still very evenly balanced, and high rates have been current throughout the year. At the close some weakness was manifested which is said to be

caused by the unusual circumstance of spelter being sent to Europe from America.

	1891.	1890.	1889.

ANTIMONY.

Opened at about 72*l.* per ton, and remained very dear during the first three months of the year. It then rapidly declined, and in September as low as 38*l.* was accepted. It afterwards advanced to about 56*l.*, finally closing at about 50*l.* to 32*l.* Furnace material has been scarce and difficult to deal in.

BAR SILVER.

Dealings in this important branch of the metal trade were inaugurated last March under the auspices of the General Produce Clearing House. At the outset a moderate amount of support was given by some merchants who believed in the importance of the trade. But it was insufficient, and after about four months' working the dealings were so small that the affair has for practical purposes become lapsed. But the utility of a large open market is indisputable, and we think more will be heard of it. The price of silver has on the whole been decidedly downwards, and in view of the want of effect on quotations by the monthly lock of 4½ million oz. in the American Treasury since August 1890, it is difficult to avoid the conclusion that the over-supply is extremely great, and that if ever free coinage should be adopted it will be at an altered ratio. To day's closing rate was 43.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

1891.

21,916. G. H. Simpson and W. C. Buntin. An improved condenser. December 15.

22,089. P. Labérie. Improvements in apparatus for evaporating saccharine or other solutions or liquids. December 17.

22,248. J. Pullman and H. S. Elworthy. *See* Class XVII.

22,333. W. R. Earp. Improvements in or relating to boiler anti-incrustation compounds or compositions and in the utilisation of waste substances for their manufacture. December 21.

22,349. A. S. Newman and J. Guardia. An appliance for regulating the flow of compressed gas from cylinders or other containing vessels. December 22.

22,465. A. Kerschbaum and F. J. Zwick. *See* Class XVII.

22,474. E. Bennis. Improvements in elevating or carrying apparatus applicable for sulphate of ammonia. December 23.

22,607. D. Rylands. Improvements in furnaces, retort chambers, and the like. December 28.

22,639. E. S. Arrighi. Improvements in and in the manufacture of clinical and other thermometers, and in apparatus therefor. December 28.

22,654. T. Veevers. Improved means or apparatus for boiling and evaporating purposes. December 29.

22,655. H. Williams. *See* Class VII.

22,656. H. Williams. Improvements in the method of and in apparatus for drying malt, hops, grain, pulse, and other substances. December 29.

22,677. P. Bender and H. Stockheim. *See* Class XVII.

22,744. S. F. Samuelson and L. A. Wilstahm. Apparatus for separating liquids of different densities. December 30.

22,870. J. Pullman and H. Lane. Improvements in the construction of compressing machinery or apparatus for the condensation and liquefaction of gases. December 31.

1892.

11. E. C. Peek. Improvements in taps or cocks for liquids. Complete Specification. January 1.

116. J. Bennett. An improved method of preventing incrustation, corrosion, and pitting in steam boilers and other vessels used for converting water into steam. January 4.

138. E. Brook. Improvements in furnaces. January 4.

154. A. T. Danks. Improvements in appliances for saturating air, oxygen, or other gases with the vapours of ether or other volatile fluids. Complete Specification. January 4.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

1194. A. Chapman. Multiple-effect evaporating apparatus. December 31.

3051. L. Archbutt and R. M. Deeley. Process for treating chemically softened water so as to prevent the formation of an adherent deposit in the feed apparatus of steam boilers. December 23.

3514. B. Willcox.—From F. Fouché. Apparatus for condensing steam or vapour. January 6.

3916. F. Lennard. *See* Class II.

3952. F. Lowe. Apparatus for straining or filtering liquids. December 23.

3955. E. Luck. Improvements connected with vacuum distillatory apparatus. December 31.

4065. G. E. Belliss and A. Morecam. Machinery for compressing atmospheric air and compressing and condensing gases. January 6.

4308. E. B. Caird and T. J. Rayner. Surface condensers. January .

12,469. E. Hesketh and A. Marect. Apparatus for producing cold by the employment of carbonic anhydride. December 23.

12,676. E. Hesketh and A. Marect. Apparatus for producing cold by the employment of carbonic anhydride. December 31.

17,623. W. H. Bowers. Retorts for the carbonisation of wood and other vegetable substances, and the drying of manures, sewage, sludge, peat, and other substances and products. December 31.

19,983. J. K. Broadbent. Apparatus for regulating the supply of air to furnaces. January 6.

21,518. H. S. Elworthy. Apparatus for cooling liquids. January 13.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1891.

21,816. C. Schubel. Improvements in incandescent lamps. December 14.

21,881. W. Fairweather.—From the Aeme Liquid Fuel Co., United States. Process of and apparatus for the manufacture of gas. Complete Specification. December 15.

22,106. C. E. Bell. Improvements in coke ovens to facilitate the cooling of the coke before drawing. December 17.

22,149. A. Edelmann. Improved manufacture of artificial fuel. Complete Specification. December 18.

22,167. G. T. Beilby. Improvement in the manufacture of cyanides. December 18.

22,286. J. Hamer. An improved fire-lighter. December 21.

22,292. J. A. Yeadon and W. Adgie. Improvements in heating retorts or furnaces for the distillation of coal or other analogous purposes. December 21.

22,297. J. H. Hedley. Improvements in the production of solid substances containing petroleum. December 21.

22,340. J. Pullman and H. S. Elworthy. A new or improved process for the manufacture of carbonic acid gas and hydrogen gas, and for the separation of the two gases, and apparatus therefor. December 21.

22,347. W. L. Rowland. A process for recovering cyanides from coal-gas. Complete Specification. December 2.

1892.

24. H. Williams. Improvements in gas purifying apparatus. January 1.

322. R. Pollok, jun. Improvements in and relating to the obtaining of cyanogen compounds. January 7.

471. D. Rylands and H. Naylor. Improvements in washing and preparing and coking of smudge, slack, or other coal, and in the application of the gases resulting therefrom, and in apparatus therefor. January 9.

482. J. C. Martin. Improvements in the manufacture of coal-gas and apparatus employed therewith. January 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

764. D. Rylands and R. Potter. Improvements in flues or other similar means for conveying combustible gas from the producer to the point where such gas is consumed. January 13.

1386. J. Hargreaves. Generation and combustion of gas for smelting and heating purposes, and appliances connected therewith. January 6.

2948. J. H. R. Dinsmore. Manufacture of illuminating and heating gases. December 23.

3042. J. Y. Johnson.—From P. Nadar. Apparatus for producing artificial light for photographic and other purposes. December 23.

3475. H. M. Carter and C. E. Fraser. Manufacture of brick or briquette fuel. December 31.

3862. W. Iyson. Process of making gas and a product arising therefrom. January 13.

3916. F. Lennard. Apparatus for carburetting gas or air, or for distilling, evaporating, or concentrating. January 13.

5036. W. P. Thompson.—From J. M. A. Gerard. Treatment and desiccation of peat. January 6.

17,371. K. Laves. Improved coke furnace or oven. December 31.

19,148. J. G. Cooper. Treatment of petroleum. December 23.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATION ACCEPTED.

1891.

844. F. Lennard. Apparatus for distilling, more especially intended for distilling tar. December 23.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1891.

21,249. E. von Portheim. Manufacture of new colouring matters from naphthyl-glycines. Complete Specification. December 15.

22,167. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Improvements in the production of colouring matters. December 23.

22,623. J. Murray.—From La Soc. L. Durand, Huguenin et Cie., Switzerland. A new manufacture of colouring matters. Complete Specification. December 28.

22,641. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new colouring matters. December 28.

22,839. J. Hickisson. Improvements in the manufacture or preparation of mordants or fixers for use in connection with marking ink points or pencils. December 31.

1892.

277. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Manufacture of new colouring matters. January 6.

366. R. Holliday and Sons, Lim., and T. Holliday. Improvements in the manufacture of azo colouring matters. January 7.

367. R. Holliday and Sons, Lim., and T. Holliday. Improvements in the manufacture of a new sulpho-acid of alpha-naphthylamine and of colouring matters therewith. January 7.

375. R. Greville-Williams. Improvements in colouring matters. January 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

1616. F. L. Leech and A. Horrobin. Waterproof solution. December 23.

2805. H. H. Lake.—From Wirth and Co., Agents for A. Leonhardt and Co. Manufacture of colouring matters. December 23.

2818. O. Murray.—From The Farbwerke vormals Meister, Lucius and Brüning. Production of azo colours in discharge printing on indigo dyed fabrics. December 23.

3247. E. Coen. Manufacture of copying ink. December 31.

3439. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of azo dyes. December 23.

4543. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Manufacture of improved dyestuffs suitable for dyeing vegetable fibre with or without a mordant. January 6.

4688. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Manufacture and production of new mordant-dyeing colouring matters related to the rosaniline series. January 13.

5184. J. Y. Johnson.—From F. von Heyden. Process for the production of mono-bromo and di-bromo-para-oxybenzoic acid, suitable for conversion into proto-catechuic acid, pyro-catechuic, and the like. January 13.

20,010. H. N. F. Schaeffer. Manufacture of alizarin colours, and method of employing same in the process of dyeing. December 23.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

1891.

22,234. G. H. Wolstencroft. Improved means of and apparatus for neutralising the acid in woollen piece goods and recovering the by-products. December 19.

22,303. F. Reddaway. Improvements in and in the manufacture of oil baizes, American leather, cloth, and other waterproof fabrics. December 21.

1892.

34. O. A. Berend and H. W. Miller. Process for producing artificial cotton threads from hydro-cellulose. January 1.

209. D. E. Coe. Improvements in the manufacture of yarn from waste. Complete Specification. January 5.

243. C. Hanson. Improvements in the process of extracting deleterious matters from wool and other textile materials. January 6.

477. G. Hagemann. See Class XIX.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1891.

21,801. B. Baigh. Improvements in dyeing and apparatus therefor. December 11.

22,028. H. H. Lake.—From La Société Bonnet, Ranael, Savigny, Giraud, and Marnas, France. An improved method of printing silk and similar fabrics. December 16.

22,168. T. Lye and W. T. Lye. Improvements in the bleaching or dyeing of "chip" and "chip-plaits." December 18.

22,263. L. Kern. Improvements in the method of and apparatus for preventing the escape of noxious gases in the processes of bleaching and otherwise treating textile materials. Complete Specification. December 19.

22,437. C. Kellner. An improved process and apparatus for bleaching paper pulp and other similar vegetable substances. December 23.

22,438. C. Kellner. A process and apparatus for increasing the bleaching properties of chlorine gas. Complete Specification. December 23.

22,538. E. Zillessen, sen. Improvements in dyeing silk or half silk goods. December 24.

1892.

148. A. Dreze. Improvements in dyeing vats. January 4.

282. E. Woodcock, sen., N. O. Woodcock, and E. Woodcock, jun. An improved machine for dyeing, scouring, bleaching, sizing, carbonising, and drying. January 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3385. W. Watson and E. Bentz. Improved method of manufacture of certain compounds of chromium used in dyeing and calico printing. December 31.

20,010. H. N. F. Schaeffer. Manufacture of alizarin colours, and method of employing same in the process of dyeing. December 23.

20,866. F. Hughes.—From A. Tiberghien. Dyeing, mordanting, or bleaching textile fibres. January 6.

20,931. L. Weldon. Yarn-dyeing machines. January 6.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

1891.

21,969. E. J. Barbier. Process for the treatment of bisulphate of soda and mixtures thereof with other substances for the purpose of producing neutral sulphate of soda, sulphuric acid, nitric acid, hydrochloric acid, and other products. December 15.

22,018. A. Vogt. Improvements in the manufacture of nitric acid. December 16.

22,320. La Soc. A. R. Pechiney et Cie. Improvements in the manufacture of chlorine. Complete Specification. Filed December 21. Date applied for July 2, 1891, being date of application in France.

22,340. J. Pullman and H. S. Elworthy. See Class H.

22,481. E. Edwards.—From O. Guttman and L. Rohrmann, Germany. An improved process for the preparation of pure nitric acid. December 23.

22,541. J. Brock and J. T. Marsh. Improvements in the manufacture of carbonates of strontium and barium. December 24.

22,558. A. M. Clark.—From The Deutsche Gold und Silber-Scheideanstalt, vormals Roessler, Germany. Improvements in the production of salts of ferricyanogen. December 27.

22,655. H. Williams. Improvements in the method of and means for recovering salts from brine and solutions, and for concentrating solutions. December 29.

22,704. H. H. Lake.—From Madame V. Hammettel, France. Improvements in apparatus for use in the concentration of sulphuric acid. December 29.

22,716. H. C. Bull. See Class IX.

22,828. J. J. Meldrum and T. F. Meldrum. Improvements in or connected with the supply of liquor to ammonia stills. December 31.

1892.

1. H. C. Bull. Improvements in or connected with the ammonia-soda process, applicable also to other purposes. January 1.

88. H. H. Lake.—From E. B. Cutten, United States. Improvements relating to the production of soda and chlorine, and to apparatus therefor. Complete Specification. January 2.

89. H. H. Lake.—From E. B. Cutten, United States. Improvements relating to the production of liquid chlorine, and to apparatus therefor. Complete Specification. January 2.

101. H. H. Lake.—From C. J. C. Wichmann, Germany. Improvements in the treatment of ferro-sodium sulphide. January 2.

192. A. S. Caldwell. Improvements in apparatus for evaporating and incinerating spent or used alkaline lyes or similar waste products. January 5.

212. S. C. C. Currie. Improvements in the art of producing insoluble chlorides direct from the metals. Complete Specification. January 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3345. J. S. Fairfax.—From F. Crane. Sulphuretted solutions and compounds used for the production of films or coatings. December 23.

3657. J. J. Howitt. Apparatus for the manufacture of carbonates of soda. January 6.

3785. J. Simpson. Treatment of a certain material (mineral) containing phosphate of lime for the purpose of obtaining the latter in a highly concentrated condition as dialcic phosphate, together with certain by-products. January 13.

4068. F. M. Lyte. Production of chlorine. December 31.

20,037. C. Kellner. Apparatus for the manufacture or production of bleaching powder. January 13.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

1891.

21,826. M. Epstein. Improvements in filtering tubes with ball filtering material for purifying molten glass. Complete Specification. December 14.

21,997. J. K. Thompson. An improved fire-resisting brick and material for lining, facing, or coating fire-places, fire-boxes, furnaces, ovens, and kilns of every kind. Complete Specification. December 16.

22,354. E. T. Smith. Improvements in the art of decorating earthenware. December 22.

1892.

16. R. F. Yorke. Improvements in earthenware pipes. January 1.

117. D. Rylands. Jars and similar receptacles for sterilised milk and similar preparations. January 4.

118. T. J. Shaw. An air-tight salmon and preserve jar made in earthenware, china, glass, stoneware, or any metallic substance. January 4.

165. T. H. Hunt. Improvements in appliances employed in the glazing of earthenware pipes, tiles, and analogous articles. January 5.

489. H. Warrington. Improvements in kilns or ovens for bricks, earthenware, porcelain, and similar material. Complete Specification. January 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3532. C. Breuer. Manufacturing artificial stones with glass surfaces. January 6.

18,939. J. W. Bonta. Method of and apparatus for rolling plate or sheet glass. December 31.

20,437. W. P. Thompson.—From R. S. Pease. Method and apparatus for manufacturing plate-glass. December 31.

20,439. W. P. Thompson.—From R. S. Pease. New or improved method of and apparatus for the manufacture of glass plates, cylinders, pipes, and certain other bodies. December 31.

21,350. F. Welz. Process of making rose or orange-red stained glass. January 13.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1891.

22,111. E. Nelson. Improvements in material for use as a damp course in building foundations. December 17.

22,171. T. Smith. Improvements in metallic compounds or cements, and in the methods of making and using the same. December 18.

22,198. F. H. Willis and R. Astley. An improved form of fireproof floor. December 19.

22,243. T. Bretherton. Ironcrete pavement. December 19.

22,428. J. Jackson. Improved manufacture or production of decorative material, more especially intended for application to walls, ceilings, or like surfaces. December 23.

22,716. H. C. Ball. Improvements in the production of and apparatus for obtaining carbonic acid gas and lime. Complete Specification. December 30.

1892.

50. P. A. Moreau. Improvements in the manufacture of artificial marble. January 1.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,918. C. G. Wernaer and O. Wernaer. Method of manufacturing artificial granite and marble. December 23.

1891.

1449. A. J. B. Ward. Fireproof floors, staircases, and roofs. December 31.

3532. C. Breuer. See Class VIII.

3797. G. H. Skelsey. Manufacture of Portland cement. January 13.

12,429. F. J. Reynolds and J. Brown. Building cements. December 31.

13,491. C. H. Kopke. Improved fireproof material. December 31.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

1891.

21,835. J. Harvey. Separating tin and other ores. December 14.

21,950. W. P. Breeding.—From The Agax Metal Co., United States. Improvements in the cleaning and preparation of metallic sheets and other articles, and in the coating of same with lead or alloys of same. December 15.

22,041. C. James. An improved method of treating plumbiferous copper mattes and ores. Complete Specification. December 16.

22,042. A. Walker. An improved process of extracting gold and silver from refractory and other ores containing those metals. December 17.

22,097. J. B. Alagaray. Improvements in metal alloys. December 17.

22,098. J. B. Alzugaray. Improvements in metallic alloys. December 17.

22,177. T. J. Tresidder. Improvements in the manufacture of armour plates. Complete Specification. Filed December 18. Date applied for September 3rd, 1891, being date of application in France.

22,207. C. J. L. Leffler. Alloys of lead. December 19.

22,504. I. S. McDougall. Improvements in furnaces for burning ores containing sulphur and sulphur compounds. December 24.

22,694. E. Dor. A novel system of regenerative gas furnace for the reduction of zinc ores. Complete Specification. December 29.

1892.

53. J. Pullman and H. Lane. Improvements in the manufacture of shell for ordnance of forged steel, iron, or other malleable metal. January 1.

261. T. D. Bottomuc. Tempering anti-friction and other white metals. January 6.

392. H. Hall. Improvements in apparatus for coating metal plates with tin, terne, or other metals or alloys. January 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,966. J. B. Hannay. Improvements in extracting precious metals from ores or minerals containing them. December 31.

19,181. J. B. Hannay. Process and apparatus for extracting gold from minerals containing it. December 31.

21,009. G. H. Smith and B. Cooper. Method and means for casting white metal couplings and other similar white metal objects required to stand confined pressure. October 28.

1891.

1161. B. H. Thwaite. An improved form of high temperature furnace especially adapted for the conversion of a high carbide of iron into the low carbide condition known as steel. January 13.

2747. W. Hutchinson and F. W. Harbord. The utilisation of blast-furnace and other slags in conjunction with finely-divided oxides of iron. December 23.

3278. A. French and W. Stewart. Obtaining gold, silver, and copper from ores. December 31.

20,977. J. H. Hunt. Method of reducing the bulk of scrap iron or other metals. January 6.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

1891.

21,870. H. H. Lake.—From E. A. Clark, United States. Improvements in voltaic cells or batteries. Complete Specification. December 15.

21,959. E. Hermite and A. Dubosc. Improvements in and apparatus for the manufacture of alkaline or earthy alkaline bases and of their salts or compounds by electrolysis of saline solutions. December 15.

22,030. C. Hoepfner. Improvements in the electrolytic treatment of copper and silver ores. December 16.

22,126. A. E. Porter. An improvement in secondary batteries. December 17.

22,178. F. Morin. Improvements in electric accumulators or secondary batteries. December 18.

22,339. N. Wladimiroff. Improvements in primary and secondary batteries. December 21.

22,482. H. H. Lake.—From E. Weston, United States. Improvements in voltaic cells. Complete Specification. December 23.

22,554. H. H. Leigh.—From J. F. Weyde and F. Clas, Austria, and J. Elsner, France. Improvements in batteries and accumulators. December 24.

22,708. W. Hellesen. Improvements in the manufacture of porous carbon for galvanic batteries and for filters. December 29.

22,851. E. Placet and J. Bonnet. Improvements relating to the electrolysis of metals. Filed December 31. Date applied for July 17, 1891, being date of application in France.

22,855. E. Placet and J. Bonnet. A method of extracting chromium by the aid of electrolytic baths with a base of salts of chromium. Filed December 31. Date applied for July 17, 1891, being date of application in France.

22,856. E. Placet and J. Bonnet. A method of extracting chromium by the aid of electrolytic baths with chromic acid base. Date applied for July 17, 1891, being date of application in France.

1892.

334. H. Nehmer. Improved form of a dry galvanic element. January 7.

355. E. C. Furby. Improvements in or relating to the electro-deposition of tin upon metals. January 7.

372. N. Benardos. Improvements in soldering, melting, and coating metals by the aid of electricity. January 7.

495. G. H. Robertson. An improved electric battery electrolytic. January 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

20,838. H. Birkbeck.—From O. Henriksen. New or improved couple or element for electrical purposes. December 23.

21,031. P. J. Davies. Production of lead plates for secondary batteries, and the connections, straps, or lugs to the same. December 23.

1891.

2518. W. Gibbings. Method of depositing copper or other metals by electrolysis, with the object of refining it or them, or of recovering the precious and (or) other metals contained in or alloyed with the metal under treatment. January 13.

3170. D. Rylands. Manufacture of Leclanché cells. December 31.

3738. J. Marx. Apparatus for electrolysing and bleaching. January 6.

11,702. H. Hauser. Secondary batteries. January 6.

19,900. W. P. Thompson.—From C. L. Coffin. Welding or working metals electrically. December 31.

19,901. W. P. Thompson.—From C. L. Coffin. Welding or working metals electrically. December 23.

21,442. H. H. Lake.—From I. L. Roberts. Secondary or storage batteries. January 13.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

1891.

22,297. J. H. Hedley. See Class II.

22,363. J. Kennedy. An improved soap. December 22.

22,413. W. Saint-Martin. See Class XVII.

22,430. A. Smith. Improvements in apparatus for separating certain impurities from oil, and especially from oil which has been used in lubricating machinery. December 23.

20,512. R. R. Graf. Method of treating oils used for lubricating and tempering purposes to render the same incombustible or fireproof.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

1891.

22,331. W. R. Earp. A new or improved material which may be used in arts and manufactures in the stead of india-rubber, gutta-percha, and other similar substances, and process for making the same and for the utilisation thereof of waste liquors from tanneries. December 21.

22,348. W. Grimshaw. An improved mode of making up for sale certain colour and pigment preparations for laundry and other purposes. December 22.

22,391. R. B. Johnson and T. C. Palmer. Improvements in the manufacture of white lead and apparatus therefor. December 22.

22,610. A. O. Gill and W. S. Gill. Improvements in and relating to paints and lacquers. December 28.

22,809. M. Williams. Improvement in the manufacture of oil paints and paint medium. December 31.

1892.

81. R. Matthews and J. Noad. Improvements in the treatment of oxide of lead in the production of white lead or pigments, and certain by-products. January 2.

134. W. J. Beale. Improvements in the production of substances for elastic tyres for the wheels of road vehicles, applicable to other purposes. January 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3573. T. Holden. Improved anti-fouling compound or preparation for bright or polished metallic surfaces. January 6.

21,515. E. Waller and C. A. Sniffen. Manufacture of white lead and neutral lead acetate from lead ores. January 13.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3176. W. Bolt. A process for tanning all kinds of hides or skins. December 31.

3910. O. Brunner. Waterproofing leather. January 13.

4385. A. Focking. Clarifying and bleaching tannin extracts or tannin liquors. January 13.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

1891.

22,192. L. Lamattina. Improvements relating to the conversion into manure of the refuse and foul matter from cities and towns. Complete Specification. December 18.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATIONS.

1891.

22,089. P. Labérie. Improvements in apparatus for evaporating saccharine or other solutions or liquids. December 17.

22,679. C. M. Higgins. Improvements in mucilages, sizes, and adhesive compounds. Complete Specification. December 29.

22,682. C. M. Higgins. Improvements in mucilages, sizes, and adhesive compounds. Complete Specification. December 29.

22,685. C. M. Higgins. Improvements in mucilages, sizes, and adhesive compounds. Complete Specification. December 29.

1892.

420. E. Langen. Improvements in refining sugar. Complete Specification. January 8.

XVII.—BREWING, WINES, SPIRITS, ETC.

APPLICATIONS.

1891.

22,124. C. H. Jolliffe. Improved means and apparatus for rousing, aerating, and attenuating brewers' worts during the process of fermentation. Complete Specification. December 17.

22,248. J. Pullman and H. S. Elworthy. A method of and appliances for the collection, purification, and utilisation of carbonic acid gas given off during fermentation of saccharine and other substances. December 19.

22,399. W. P. Thompson. — From O. E. Nycander, Germany. Improvements in or in the preparation of extracts for use in the manufacture of yeast and spirit. December 22.

22,413. W. Saint-Martin. Improvements in means or apparatus for maturing and improving fermented alcoholic and oleaginous liquids. December 22.

22,432. A. Fremdlich. Process and apparatus for recovering certain lye-products from the waste gases or vapours of breweries. December 23.

22,465. A. Kerschbaum and F. J. Zwick. Improvements in fermenting and apparatus therefor. December 23.

22,606. W. G. Barrett. Improvements in the manufacture of beers of low alcoholic strength. December 28.

22,677. P. Bender and H. Stockheim. Improvements in and connected with apparatus for cooling beer or other liquids. December 29.

1892.

301. H. Prior. Improvements in apparatus for cooling and attenuating beer during fermentation. January 6.

192. B. J. B. Mills.—From T. W. Q. Honeywill, New Zealand. Improvements in or connected with brewers' cleansers. January 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3207. G. F. Relfern.—From J. Hradil. Method of increasing the formation of cells during the process of fermentation. December 31.

3378. F. L. Calmant. The manufacture of charcoal from sawdust, wood shavings, and the like, and the treatment of wine alcohol, brandy, cider, beer, and other matters therewith. January 13.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

1891.

22,229. W. McDonnell. Improvements in the process of manufacturing margarine. December 19.

22,631. J. Torbitt. A method of treating the fruit of the potato plant (*Solanum tuberosum*) for its utilisation for alimentary purposes. December 28.

1892.

96. J. Fordred. An improved malted food. January 2.

279. A. D. McKay. A new chemical food. Complete Specification. January 6.

B.—Sanitary Chemistry.

1891.

22,442. J. Hanson. Improvements in the treatment of sewage and other foul liquid or semi-liquid matters for the clarification, disinfection, and deodorisation thereof. December 23.

22,531. W. Horsfall. Improvements in furnaces for destroying the refuse and dealing with the sewage, sludge, and other offensive material of towns. Complete Specification. December 24.

22,545. C. E. Bell. Improvements in the treatment of iron ores to render them suitable for use in the purification of impure waters and other liquids and gases. December 24.

22,546. W. Lawrence. Improvements in the clarification, purification, and softening of water, contaminated water or sewage in the preparation of reagents, and in apparatus for use therein. December 24.

22,747. J. T. Wood. A new or improved method or process for purifying sewage or foul water. Complete Specification. December 30.

C.—Disinfectants.

22,258. C. C. Leathers. A new or improved apparatus for disinfecting or odorising purposes. December 19.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

21,019. E. Sonstadt. Making an extract of coffee and confection of the same, and in preserving liquid coffee extracts. December 31.

21,106. E. Sonstadt. Making an extract of tea and a confection of the same, and preserving liquid tea extracts. December 31.

1891.

2816. O. Murray.—From Calberla, Fitz and Consorten. Process and apparatus for sterilising liquids. January 13.

2944. J. Oakhill and R. H. Leaker. Process for preserving milk. January 13.

19,887. H. S. Elworthy. Preserving meat, fruits, and such like perishable articles in store or in transit. January 6.

21,372. J. Carnrick. Manufacturing kumyss compounds or kumyss tablets. January 13.

B.—Sanitary Chemistry.

1891.

2816. A. McDougall and J. J. Meldrum. Disinfection and deodorisation of sewage, and apparatus for preparing and applying the disinfectant. December 23.

5908. E. E. Dulier. Method of destroying smoke, and apparatus for that purpose. January 6.

14,735. E. Devonshire. Apparatus for purifying or treating water. December 31.

17,623. W. H. Bowers. *See Class I.*

20,726. J. Norris. Disposal of sewage and apparatus connected therewith. January 6.

C.—Disinfectants.

1891.

9083. C. Scott. Method of vaporising eucalypt and other disinfectants, and apparatus therefor. January 6.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

1892.

433. H. Richardson and H. Glenny. Improvements in the manufacture of paper and in apparatus used for that purpose. January 8.

477. G. Hagenmann. Improvements in the manufacture or production of cellular substance suitable for paper-making and fibre suitable for spinning. January 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3878. R. N. Redmayne. Manufacture of paper pulp for paper-making and other purposes. January 6.

5240. J. Valetton. New or improved anti-nicotine cigarette paper. January 13.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES,
AND EXTRACTS.

APPLICATIONS.

1891.

22,253. L. J. P. Pontallic. Improved apparatus for obtaining products of distillation, or separating volatile liquids. Complete Specification. December 19.

22,787. C. Fahlberg. Improvement in the production of pure saccharine. December 30.

1892.

361. C. D. Abel.—From C. F. Boehringer and Sohne, Germany. Improved manufacture of vanillin. January 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

21,019. E. Sonstadt. *See Class XVIII.—A.*

21,106. E. Sonstadt. *See Class XVIII.—A.*

XXI.—PHOTOGRAPHIC PROCESSES AND
MATERIALS.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

7635. E. Hackh. Magnesium lights for photographic and signalling purposes. December 23.

16,125. A. Hill. Enlarging photographic gelatin films by the aid of chemical means and without the aid of enlarging apparatus. December 23.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

1891.

21,879. A. Ruston and E. Beadle. Improvement in railway fog signal detonators. Complete Specification. December 15.

22,401. J. Tinsley. Improvements in explosives. December 22.

1892.

41. J. Wilson. Improvements in cartridges applicable for blasting purposes. January 1.

COMPLETE SPECIFICATION ACCEPTED.

1891.

3881. G. A. Rosenkolter. Manufacture of lucifer matches. December 31.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—Vol. XI.]

FEBRUARY 29, 1892.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers: Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	F. Hurter, Ph.D.
L. Archibutt.	C. C. Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	B. E. R. Newlands.
E. Rider Cook.	John Pattinson.
W. Y. Dent.	W. H. Perkin, Ph.D., F.R.S.
Chas. Dreyfus, Ph.D.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. E. Hewitt, M.D.	A. Norman Tate.
David Howard.	Wm. Thorp.
Prof. J. J. Hummel.	Thomas Tyrer.
Prof. A. K. Huntington.	

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	F. H. Leeds. III., XXI.

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, January, February, and April 1886, and February 1889. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd FEBRUARY 1892.

- Auchincloss, David L., Park Hall, Dalmeir, N.B., student.
 Ballard, Ernest, Colwall, Great Malvern, malt vinegar brewer.
 Bayne, Prof. Jas., Chemical Laboratory, Royal Veterinary College, Camden Town, N.W., professor of chemistry.
 Beckworth, W. Harold, Hotham House, Haddingley, Leeds, tanner and leather manufacturer.
 Brown, Reginald B., Ellerslie, Knighton Park Road, Leicester, dyer's chemist.
 Burrough, Horace, jun., c/o Massachusetts Institute of Technology, Boston, U.S.A., technical chemist.
 Butterfield, Horace V., 16, Thistlewaite Road, Clapton, N.E., foreman warehouseman.
 Clark, Durand G., 53, Chancery Lane, W.C., analytical chemist.
 Colquhoun, Lewis, Ardeer Ironworks, Stevenston, Ayrshire, analytical chemist.
 Croft, Jos., 26, Beeston Road, Dunkirk, near Nottingham, leather dyer.
 Cullen, Wm., jun., Ardeer Terrace, Stevenston, Ayrshire, chemist.
 Entwisle, Edw., Alder Bank, Pendleton, Manchester, cotton manufacturer.
 Guthrie, Jno., 50, Prospect Terrace, Hunslet Moor, Leeds, chemical works manager.
 Guttmann, Oscar, 110, Adelaide Road, N.W., explosives engineer.
 Hadfield, Thos., Garrison Bleach Works, Birch Vale, near Stockport, manager.
 Harrison, Prof. J. B., Government Laboratory, Georgetown, British Guiana, Government analyst.
 Heslop, Oliver, 110, Rye Hill, Newcastle-on-Tyne, analytical chemist.
 Hobbday, Thos., c/o All-sopp and Sons, Lim., 52, Granby Street, Leicester, brewer.
 Holland, Philip H., 958, Sherbrooke Street, Montreal, Canada, merchant.
 Hosie, Geo. H., Nobel's Villas, Stevenston, Ayrshire, N.B., technical chemist.
 Jennison, Francis D., c/o A. Hingworth, Esq., Moscow, Russia, dyer.
 Lucas, Bernard R., 5, St. John's Terrace, Middlesbrough, alkali works manager.
 Macrae, Thos., jun., 138, Bath Street, Glasgow, student of chemistry.
 McLeod, Jas., 141, High Street, Dumbarton, N.B., analytical chemist.
 Mansbridge, Wm., Luther Place, Horsforth, Leeds, chemist.

Morgan, Albert J., 139, West Street, New York City, U.S.A., soap manufacturer.

Mount, Edw., Oaklands, Aughton, near Ormskirk, assistant secretary United Alkali Company.

Mummery, Albert F., 5, Castlemount Terrace, Dover, tanner.

Norman, John T., 78, Chelverton Road, Putney, S.W., consulting chemist.

Riker, John J., 15, Cedar Street, New York City, U.S.A., merchant.

Taylor, W. G. H., 3, Vernon Road, North Bow, E., analytical chemist.

Wade, Jas. L., jun., 28, West Kensington Gardens, London, W.

White, H. Osborne, 35, North Bank, Regent's Park, N.W., white lead manufacturer.

CHANGES OF ADDRESS.

Ballard, E. G., 10 Curzon Park; Newton Lane, Hoole, Chester.

Barnes, Jonathan, 10 Buckton Vale; 1, Trafalgar Street, Great Clowes Street, Manchester.

Batty, R. B., 10 Lincoln Villa; Wharncliffe, Erdington, Birmingham.

Bell, Sir Lowthian, Bart., address for subscriptions c/o Bell Bros., Middlesbrough.

Blythe, Herbert, 10 Church; 33, Leyland Road, Southport.

Bond, L. W., 10 Ensley; Box 506, Seattle, Wash., U.S.A.

Brown, F. W., 10 London; Ingleside, Sambourne, Warminster, Wilts.

Bruce, Jas., 10 Mountpottinger; The Irish Distillery, Connswater, Belfast.

Burrell, B. A., 5, Mount Preston (not Pleasant), Leeds.

Chase, R. L., Journals to 155, East Main Street, North Adams, Mass., U.S.A.

Crowther, Horace W., Journals to 21, Beeches Road, West Bromwich.

Dagger, J. H. J., Journals to Hallwater, Endon, Stoke-on-Trent.

Dupce, H. D., all communications to Walpole, Mass., U.S.A.

Earnshaw, Edwin, 10 24; 72, Mark Lane, E.C.

Elliot, A. H., 10 East 23rd Street; "Anthony's Bulletin," 591, Broadway, New York, U.S.A.

Franee, G. T., Journals to Friar's Goose Works, Gateshead-on-Tyne.

Froehling, Dr. H., 10 Richmond, Va.; Warners, Onondaga Co., N.Y., U.S.A.

Gamble, Jas. N., Journals to "The Laboratory," Procter and Gamble Co., Ivorydale, Ohio, U.S.A.

Green, Alf. H., Journals to Oaklands, Lowton, Newton-le-Willows, Lancashire.

Handy, J.O., 10 Fifth Avenue; c/o Hunt and Clapp, Pittsburgh, Pa., U.S.A.

Harmon, L. E., 10 Lockport; c/o E. Elsworth and Co., 71, Park Place, New York, U.S.A.

Hecht, Jos., 10 Philadelphia; c/o Manufacturing Investment Co., Appleton, Wis., U.S.A.

Hirsch, Dr. H., 10 Huddersfield; Potsdamerstrasse 113, Villa H., Berlin, W.

Hodges, H. B., 10 Omaha; 50, Beacon Street, Boston, Mass., U.S.A.

Howorth, F. W., 10 Urnston; c/o Lloyd Wise, 46, Lincoln's Inn Fields, W.C.

Hutchinson, C. H., 10 Church Street; Falcon Works, Sackville Street, Barnsley, Yorks.

Jones, Professor D. E., Journals to County Council Offices, Stafford.

Kent, W. J., 1/o 1218; P.O. Box 294, Johannesburg, S.A.R.

Kinnicutt, Professor L. P., Journals to 77, Elm Street, Worcester, Mass., U.S.A.

Leeds, Frank H., 1/o Stoke Newington; 26, East Bank, Stamford Hill, N.

Mabery, Dr. C. F., Journals to 9, Rockwell Street, Cleveland, Ohio, U.S.A.

Macallan, J., 1/o Marino Terrace; 3, Charlemont Terrace, Clontarf, Dublin.

Macfarlane, Jas. A. (Journals) Sta. Rosalia, Baja California, Mexico (*via* New York, Nogales, and Guaymas); and (subs.) 3, Carlyle Terrace, Kelvinside, Glasgow.

MacKenzie, Dr. W. Cossar, 1/o Newcastle; Tewfikieh College of Agriculture, Ghizeh, Egypt.

Masson, G. H. 1/o Trinidad; 16, Roseneath Place, Edinburgh.

Miller, W. M., 1/o Demerara; Maryville, Mount Vernon, near Glasgow.

Müller, G., 1/o Box 148; c/o Curry Hotel, Ironwood, Mich., U.S.A.

Nakamura, T., 1/o Mita-Nichome; 151, Shirokané-Sankochō, Shibaku, Tokyo, Japan.

Neilson, T., 1/o Whitehaven; New South Hamilton Street, Kilmarnock, N.B.

Ree, Alf., 1 (not 6), Brighton Grove, Rusholme, Manchester.

Robertson, Robt., 1/o Glasgow; Royal Gunpowder Factory, Waltham Abbey, Essex.

Saint, W. J., Journals to 11, Queen's Road, Aberdeen.

Smith, R. Greig, 1/o Musselburgh; Durham College of Science, Newcastle-on-Tyne.

Studer, S. J., 1/o Manchester; 17, Lovely Lane, Warrington.

Todd, A. M., 1/o Nottawa; 204, North Rose Street, Kakumazoo, Mich., U.S.A.

Wallace, J. Stewart, 1/o Queen Victoria Street; Copthall House, Copthall Avenue, E.C.

Walsh, P. H., Journals to 85, Joy Street, Boston, Mass., U.S.A.

Warne, Thos., 1/o Walsall; 6, Wakefield Road, Thwaitegate, Leeds.

Will, W. Watson, 1/o Putney; 1, Newington Terrace, Kennington Park, S.E.

Williams, Seward W., East Orange, N.J. (not Mass.), U.S.A.

Wood, Wm., 1/o 124; 128, Chaussée de Turnhout, Antwerp.

ADDITION TO LIST OF MEMBERS.

Jackson, V., Park Hill, 10, Chorley Old Road, Bolton.

Deaths.

Dittmar, Prof., F.R.S., Anderson's College, Glasgow. February 9.

Fearfield, J. P., Stapleford, Notts.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Vice-Chairman: W. Crowder.

Committee:

C. F. Cross.	W. Kellner.
J. Dewar.	B. Redwood.
A. G. Green.	W. S. Squire.
S. Hall.	G. N. Stoker.
C. W. Heaton.	F. Napier Sutton.
J. Heron.	Wm. Thorp.
D. Howard.	T. E. Thorpe.

Hon. Local Secretary: John Heron,
St. John's Villas, Worpole Road, Wimbledon.

SESSION 1891-92.

1892:—

March 7:—

Mr. Oscar Guttman, Assoc. M.I.C.E. "On the Dangers in the Manufacture of Explosives."

Drs. Evans and Wirtz, and Messrs. Cross and Bevan. "On the Acid Action of Drawing Paper."

April 14:—

Dr. C. R. Alder Wright, F.R.S. "On Specific Gravities for Practical Purposes."

Mr. Albert Baur, Ph.D. "On Artificial Musk."

Mr. F. H. Leeds, F.I.C., F.C.S. "Note on Rosin Oil."

Election of Officers and Five Members to the Local Committee.

Nominations must be signed by Ten Members and sent to the Secretary on or before March 22nd. Members can only sign one nomination. (See Bye-laws.)

May 2nd:—

Professor Wm. Ramsay, F.R.S., and Mr. J. C. Chorley. "The Distillation of Wood."

Dr. S. Rideal. "Notes on the Composition of some Indian Gums of known Origin."

June 6th:—

Mr. J. A. Nettleton. "Vinegar."

Dr. S. Rideal. "The Petroleum Jellies of Commerce."

Meeting held Monday, 4th January, 1892.

MR. THOS. TYRER, IN THE CHAIR.

THE CHAIRMAN, before calling on Mr. Redwood for his paper, referred to the loss the Society and the Section had sustained by the decease of the London Secretary, Mr. T. W. B. Mumford. On his motion a vote of condolence and sympathy with Mrs. Mumford and the family was passed unanimously.

The Chairman announced that in virtue of its powers under the Sectional Byelaws, the Committee had nominated Mr. John Heron, F.I.C., F.C.S., and past President of the Institute of Brewing, to be Secretary.

THE GALICIAN PETROLEUM AND OZOKERITE INDUSTRIES.

BY ROBERTSON REDWOOD, F.R.S.E., F.I.C., F.C.S.,
ASSOC. INST. C.E.

I.—Petroleum.

THE increasing consumption of petroleum in the form of lamp oil and lubricating oil, and especially the growing demand for the material in the manufacture of gas for illuminating purposes, either as a substitute for canal in enriching coal-gas or for carburetting water-gas, are rapidly tending to confer general industrial importance upon sources of supply that might otherwise have remained of merely local consequence. It is on this broad ground that the subject of the Galician petroleum industry has been thought to be not unworthy of the attention of the members of the Society of Chemical Industry.

The petroleum industry of Galicia, in common with the corresponding industries of the United States, Russia, and other countries, may properly be described as of great antiquity. From the earliest times of which any historical records have been preserved the crude oil has been collected in a primitive fashion and has been largely employed in the manufacture of cart-grease, and as a remedial agent for outward application in cases of cutaneous disease of men and animals. The oil was also, many years ago, sent into Bohemia, where it was mixed with small coal to form briquettes. In the first instance it was collected from springs and streams of water, but the old timbered oil-wells so frequently met with in Galicia and Roumania indicate

very clearly that it has long been the practice in those countries to dig wells or shafts for the collection of the oil. The petroleum of Galicia is specially referred to in local records from the commencement of the seventeenth century, but evidently was not at that early date regarded as having any commercial importance, for as Mr. Nelson Boyd, M.I.C.E., has pointed out, it was not mentioned in the Austrian mining laws framed in 1786, and applicable to Poland. It was not, in fact, until 1810 that petroleum appears to have been first officially noticed in a Government decree relating to the registration of mining rights. There are no statistics from which any accurate impressions of the extent of the industry at this early period can be gathered, but it may safely be assumed that the requirements of a sparse population, far removed from the civilising influence of the capitals of Europe, cannot have been considerable. It was not in fact until the manufacture from the raw material of an oil for use in lamps was commenced that the industry assumed industrial importance, and the pit-wells were found inadequate to meet the rapidly increasing demands.

In the United States the petroleum industry in its present form is generally considered to date from the drilling of what is known as the Drake well in 1859, but long before this time systematic attempts were made in Galicia to found a business in the refining of the oil. As far back as 1810, or between that date and 1818, Hecker and Mitis, who owned wells in the Dohobycz district, are reported to have distilled the oil, and the Alstettering in Prague is stated to have been lighted with the product. The refinery from which the city received its annual supplies of 300 cwt. was situated at Kabcza, and the oil appeared to have been sold at 35 florins per cwt. This business, however, came to an end in 1818, and no further attempt to supply an oil suitable for use in lamps appears to have been made until 1852. In that year, a manufacturer of cart-grease, of the name of Schreiner, collected some of the liquid which condensed on the cover of the vessel in which he was accustomed to heat the crude petroleum. This strong-smelling oil he took to an apothecary named Mikolash, whose assistants, Lukasiewicz and Zeh, treated it with sulphuric acid and caustic soda. This refined oil was found to burn so well that renewed attention was at once directed to the subject. In the following year Galician petroleum was substituted for candles in the lighting of the station of the Emperor Ferdinand's North Railroad, and in 1854 the oil became an article of commerce in Vienna.

In 1859 one of two brine-wells in the Sloboda-Rungurska district of Galicia, excavated as far back as 1771, and stated to have continuously yielded a small quantity of petroleum, was deepened to 25 metres, with the result of increasing the yield. This historic well, which bears the name of Stanislaw, appears to have been further deepened by digging, in 1865, to 50 metres, the original diameter of 1.50 metres being preserved to the bottom. It is stated by Babu* to have yielded then five barrels a day, and this production was not sensibly altered by an attempt in 1875 to increase it by drilling from the bottom of the shaft to a further depth of 100 metres, making 150 metres in all. In 1884 the depth of the well was further increased by drilling to 213 metres, and the yield of oil was thereby augmented to 10 barrels a day.

It was, however, in what is known as the Bobrka district that the earliest systematic development of the industry occurred, and when the writer visited the Galician oil-fields in 1887 he was pleased to see that a stone obelisk had very properly been erected in this district by Klobassa and Tszczieski, the owners of neighbouring petroleum properties, to record the fact. The monument bears an inscription of which the following is a translation:—"To preserve the memory of the founding of the petroleum mine in Bobrka in the year 1854 by Ignacy Lukasiewicz. 4th Nov. 1872."

Bobrka is a village on the left bank of the Jasolka, between Krosno and Dukla, and it was here that after many comparatively unsuccessful attempts to collect the petroleum by the digging of long trenches about a metre deep, and shallow wells, Lukasiewicz, with the co-operation of M. Klobassa, completed in 1861 the first important well, which, at a depth of 14 metres, yielded 6,000 kilogrammes of oil

per hour. The work of development was thenceforward proceeded with, and the production quickly assumed locally important dimensions.

The active development of the Sloboda-Rungurska section of the Kolomea oil-field was commenced in 1881, and in 1883 this district was reported to be yielding 550 barrels per diem of crude petroleum within an area of 1,500 metres in length and from 350 to 500 metres in breadth. The Sloboda-Rungurska field was for a time by far the most productive of the Galician oil-territories, the production at one period having increased to over 1,600 barrels per day. In consequence of the compact character of the petroliferous area, and the apparent regularity of the distribution of the oil over this area, the drilling of wells within the demarcated oil zone in this district has been attended with comparatively uniform success.

Meanwhile the development of the portion of the oil-belt in the neighbourhood of Ustrzyki has been steadily progressing, and there is now no part of the Galician oil-fields where the industry is more firmly established or where the prospects are more favourable.

Concurrently with the recent progress made in the Ustrzyki section of the belt renewed attention has been given to the western end, and at Wietzno some remarkably productive wells have been drilled. The Wietzno field joins the Bobrka district, where the petroleum industry of Galicia may, as already pointed out, be said to have had its birth. The neighbourhood of Krosno constitutes another portion of the western end of the oil-belt in which the efforts of the producer have quite recently met with conspicuous success, several very productive wells having been drilled here.

The province of Galicia was originally a portion of the kingdom of Poland. It was allotted to Austria at the time of the partition in 1776, and is now embraced in the Empire of Austria-Hungary. A glance at the map of Europe will show that Galicia lies on the northern slopes of the Carpathian mountains, which extend in a general north-westerly and south-easterly direction.

In this connexion it may be well to point out that the principal petroleum deposits occurring in various parts of the world are closely associated with the chief mountain ranges. In illustration of this statement attention may be directed to the accompanying map of Europe (Map No. 1), on which some of the chief petroliferous districts, deposits not yet of industrial importance, and localities where indications of petroleum have been met with, are marked.

Commencing, at the extreme eastern confines of Europe, with the very important oil-fields in the neighbourhood of Baku, evidences of the existence of the oil are found at many points along the Caucasus mountain range between Baku and the Black Sea coast, notably in the neighbourhood of Tiflis, and between Poti and Batoum. On the Taman peninsula, inland of Novorossisk, lie the oil-fields of Illsky and Kondako, and farther westward are the well-known petroleum deposits of Kertch, in the Crimea.

Still travelling westward, the Carpathian ranges are reached, and here, in addition to the Galician oil-territory, which as already stated lies on the northern slopes of those mountains, there are the important Roumanian oil-fields occupying the south-eastern and southern slopes of the Southern Carpathians, or Transylvanian Alps, and deposits which as yet are of comparatively small commercial importance in the Bukowina, Transylvania, and Hungary.

An extension of the same general south-easterly and north-westerly line will pass through the neighbourhood of Hanover, where petroleum is now being obtained.

Parallel to this long line of petroleum-producing localities, but considerably to the south of it, there is a series of localities where petroleum indications are said to occur on the coast of Dalmatia and Albania, near the Dinaric Alps and Pindus mountains, and to the north-westward of these indications is situated the somewhat important oil-field of Alsace, bordered by the Vosges mountains.

Still further south is another north-westerly and south-easterly line of oil-bearing rocks in Italy following the general direction of the Apennines, and to the south-eastward is the island of Zante, where the historic petroleum spring of Herodotus may still be seen.

It may be suggested that the oil deposits of Sicily lie on a further parallel line, and it will be observed that such a

* Ann. des Mines, Ser. XIV., 102-1206.

line prolonged to the north-westward would not pass far northward of the Pyrenees, where petroleum has also been met with.

In Spain petroleum has been found not only in the north, but also, it is said, in the south near Seville, not far distant from the Sierra Nevada mountains, and if a line parallel to those already referred to be drawn through the latter in a south-easterly direction it will intersect the Algerian oil deposits in the neighbourhood of Oran, with the Atlas mountains not far inland.

Reverting once more to the Galician oil-fields, attention may be drawn to the importance of their geographical position, for they lie, as will be seen, almost exactly in the centre of Europe. The "oil-belt," as far as it has yet been defined, has a length of some 220 miles with a breadth of from 40 to 60 miles, and it extends, as already indicated, in a general north-westerly and south-easterly direction.

The precise positions of the various petroleum-producing properties, as well as of localities where promising oil-indications occur, are very clearly shown in the series of three maps (Maps Nos. 2, 3, and 4) which have been drawn for this paper. The situations of the respective areas of these maps are indicated on the map of the kingdom of Austria-Hungary (Map No. 5). To all these maps further reference will be made under the heads of production and refining. The country, as will be seen from the series of three maps, is to a large extent of a mountainous character, but it is for the most part well provided with good roads and most of the developed properties are within a short distance of the railway.

The Carpathians form a long curved range of mountains separating Hungary and Transylvania on the north, east, and south-east from Silesia, Galicia, Bukowina, Moldavia, and Wallachia. The inner curve of this range consists largely of precipitous masses of rock, while the outer slope descends gradually to the Tertiary plains of Galicia and Roumania by a descending series of parallel folds. At the foot of the slope is a deposit of rock salt extending through Galicia and Bukowina into Moldavia. On the northern declivity in Galicia the Cretaceous formation is covered with a deposit of Eocene rocks and the whole surface has been thrown into a series of ridges, the denuded crests of which exhibit the successive layers. Heurtean* points out that the rarity of fossils in these beds renders their classification very difficult; it is, however, agreed that they are of the latest period of the Cretaceous age or of the Eocene age. To these rocks as a whole the name of Carpathian sandstone has been given. A portion of this sandstone is bordered by a deposit of the Miocene age. C. M. Paul, who has carefully studied the geology of the Carpathians,

asserts that in the neighbourhood of Cracow the Cretaceous formation met with is only in a rudimentary stage, while the Tertiary formation is fully developed. He describes the four following distinct groups in descending order:—

1. *Magura Sandstone*.—Quartzose noncalcareous sandstone, alternated with grey or whitish laminated clays, which separate the beds of friable and shaly white micaceous sandstone containing vegetable remains. In this formation white or blue hydraulic marl is also met with, and at the base is also found a characteristic quartzose conglomerate. Fish remains also occur. This belongs to the close of the Eocene period.

2. *Smilno Schiefer*.—Black laminated and contorted shales, characterised by layers of flint and sphaeroidite.

3. *Belowesa Schiefer*.—Hieroglyphic sandstone and red shales in thin layers, very micaceous. To this horizon belongs also the brown sandstone in thick layers, permeated by veins of spathic limestone and sandstone in thin laminae, with fucoids.

4. *Ropianska-Schiefer*.—Shaly beds, micaceous and quartzose, usually bluish-grey, containing layers of sandstone very difficult to distinguish from those of the upper deposits. At Ropianska these beds lie on a greyish sandstone of medium grain completely saturated with petroleum.

The slopes of the Carpathians thus consist of Cretaceous and Tertiary limestones, sandstones, and shales overlying a mass of metamorphic rocks. The shales are for the most part rich in vegetable and animal remains, this being particularly noticeable in East Galicia and the Bukowina, where thick beds of black bituminous shale are met with. The petroleum occurs in both coarse and fine sandstone, chiefly of the Eocene and Miocene ages, but it doubtless was formed in the shale. The oil-bearing formation lies, as already stated, in parallel folds, and the petroleum is found in great abundance under or near to the crests of the anticlinals. Rock-salt, gypsum, native sulphur and various sulphides, blende, pyrites and galena are met with in association with the petroleum. Sulphuretted hydrogen is also a frequent concomitant.

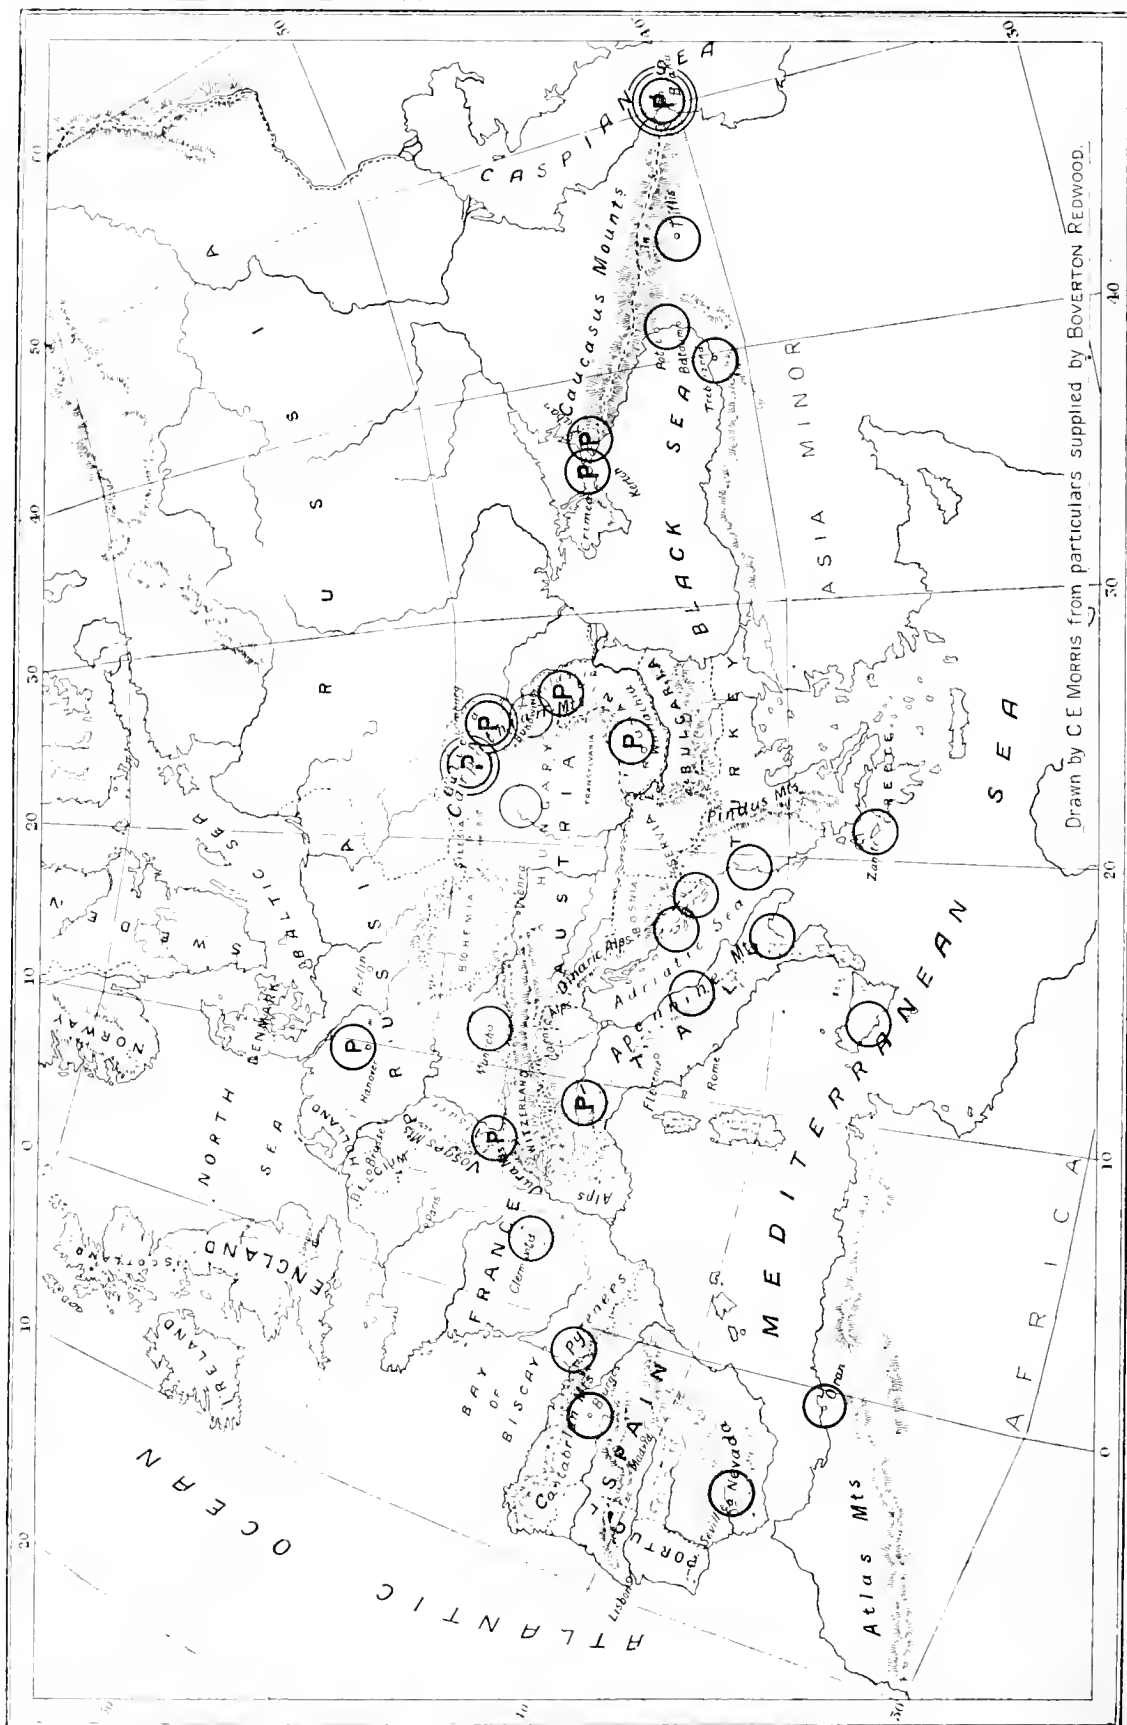

Of the petroliferous formation in the Ustrzyki district, Paul remarks that the alternating layers of shales, clays, and sandstones of which it is composed belong to the early Eocene age, therefore to the same geological horizon as the oil-bearing rocks at Bobrka, Płowiec, Uherce, and Schodnica. The overlying beds are of later Eocene age, and the underlying have not yet been opened up.

In the following table by Rateau† some of the petroleum-producing localities in Hungary and Galicia are classified geologically:—

Formation.	Division.	Local Names.	Deposits.	
			Hungary.	Galicia and Bukowina.
Neogene.....	Salzhongruppe	Reetz, Kovac, Garbomac, Dragomer, Sossmezo.	Boryslaw, Staranin, Dwiniacz.
Eocene	Upper	Szipot beds, Kliwa sandstone, Magura sandstone.	Upper Hungary and Transylvania.	Wherever the menilite shale assumes a sandy character.
	Middle	Menilite shale	Smilno, Szimna, Marmaros, Iod, Dragomer.	Libusa, Bobrka, Barvynick, Polany, Baryslaw, Wyskow, Moldawitz.
	Lower	Libusa sandstone	Marmaros, Zibo, Udvarhely, Sossmezo.	Libusa, Harklowa, Bobrka, Sanok, Polany.
Neocomian	Calcareous sandstone with nummulites	Upper beds with Hieroglyphs and fucoids.	Konyha, Sacstal.	Maukova, Ustrzyki, Pohar, Polany, Sloboda-Rungurska.
		Lower beds with Hieroglyphs and fucoids.	Prozolina, Sossmezo.	Schodnica, Maltawitz, Mraznica, Barvynick.
	Upper	Ropianska beds	Mikowa, Luch.	Ropianska, Sary, Ropa.
	Middle	Wernsdorf beds	Komarnik	Kowali, Brzisko, Kleczany.
	Lower	Teschen shales	Arva, Liptau.	Biala, Kimpolung.

MAP No. 1.—OCCURRENCE OF PETROLEUM IN EUROPE.

The more important deposits are marked P in a circle. The Galician fields are distinguished by two concentric circles, and the Baku fields by three concentric circles.

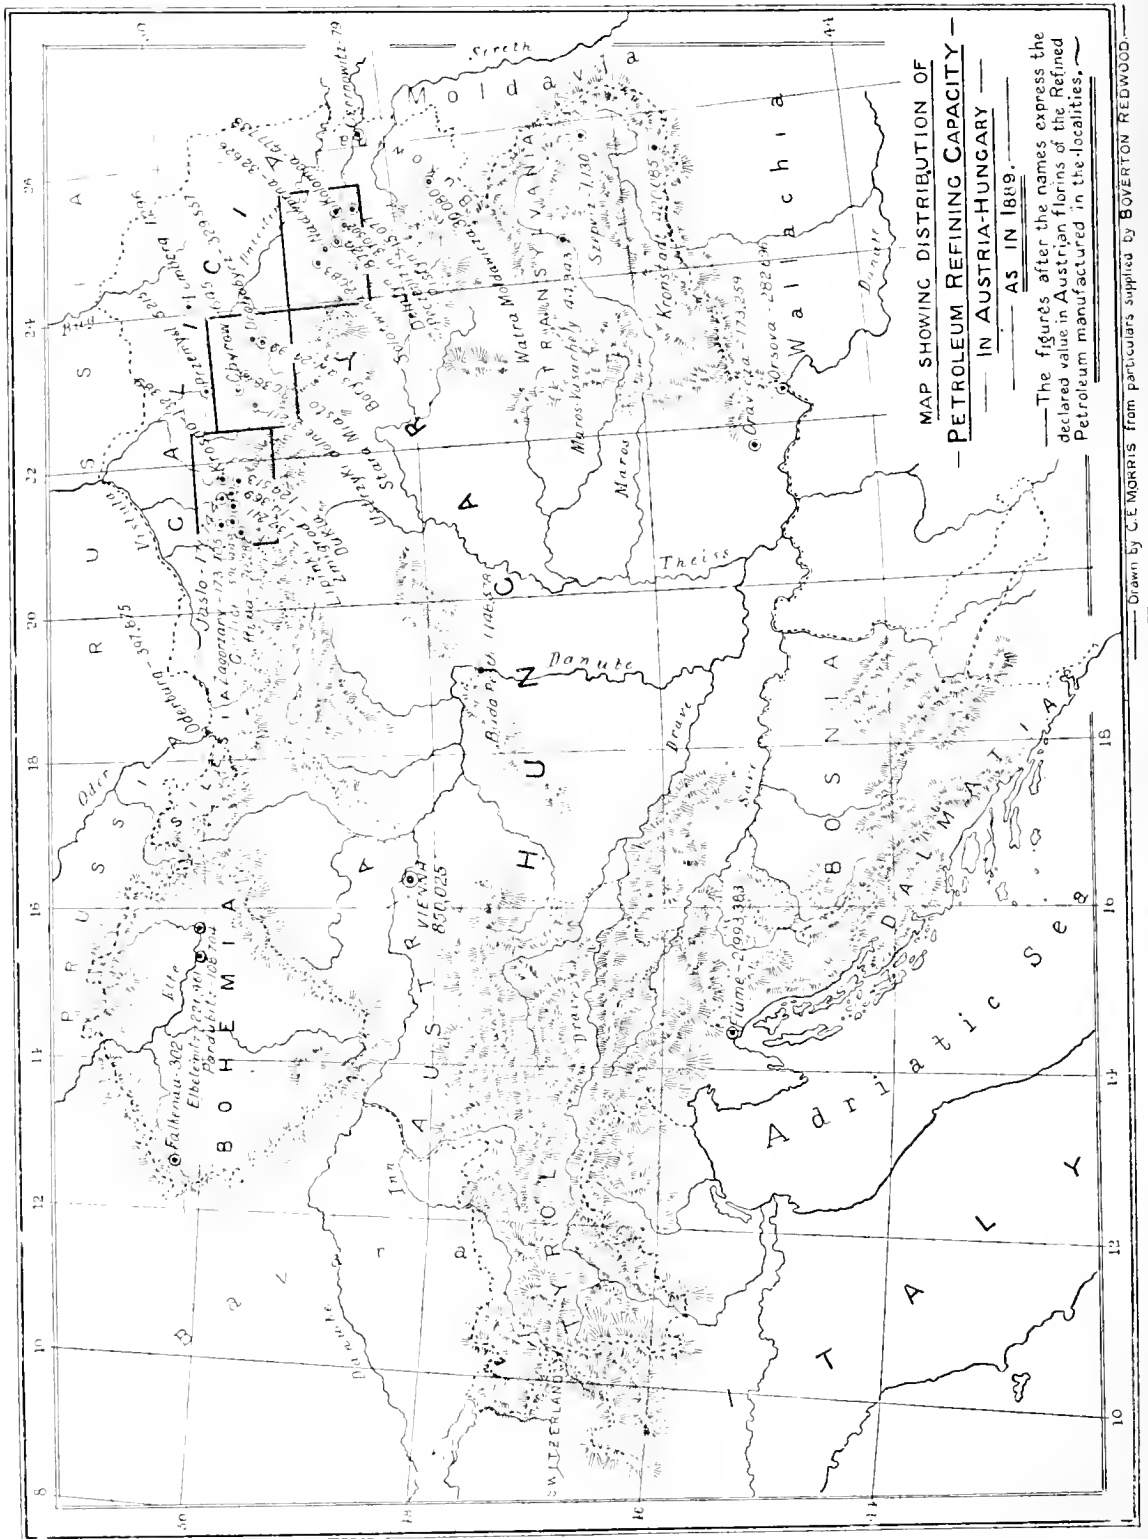

MAP No. 3.—INTERMEDIATE PORTION OF GALICIAN OIL-BELT.

MAP No. 4.—EASTERN END OF GALICIAN OIL-BELT.

Mr. William Topley, F.R.S., who is well known to have devoted special attention to the geology of petroleum, has, with a kindness for which the writer cannot sufficiently thank him, furnished for this paper the following particulars of the geological occurrence of petroleum in Galicia.

The Carpathians are composed of thick masses of rock, mainly sandstones, which have been thrown into a great series of folds, trending a little south of east in West Galicia, but turning more to the south further east, and in East Galicia trending about south-east.

These sandstones, collectively termed the Carpathian sandstones, are now known to belong to the Neocomian, Cretaceous, and Lower Eocene formations; or, by comparison with well-known strata in the south-east of England, they range in age from the Lower Greensand to the London Clay.

The Eocene strata, the upper beds of which are now called Oligocene by Paul, form the rolling ground on the northern flanks of the Carpathians, whilst the flatter land to the north is formed of Miocene beds. This is a rough and general statement of the range of the beds, but the whole district is traversed by a number of folds and anticlinals, so that the Neocomian beds are brought up amongst the newer

strata; and by the extreme foldings, faults, and overthrusts to which the beds have been subjected, the older rocks seem often to overlies the newer ones.

The general succession of the strata is as follows, petroleum occurring in the divisions marked * :—

*Salt Marl beds (ozokerite)	Miocene.
Magura and Kliwa sandstones ..	Oligocene of
*Menilite beds	{ some Authors. } Eocene.
Carpathian Sandstone series {	
*Upper	Cretaceous.
Middle	
*Lower (Ropienka beds)	Neocomian.

The menilite beds take their name from the occurrence therein of menilite (a semi-opal).

Different authors employ somewhat different names in describing the beds. Some of these names may be of beds only locally developed. It is therefore sometimes difficult to correlate the various descriptions, or to get all the beds mentioned into any general classification. The following are sections given by Walter and Dunikowski, from whose work† the accompanying illustrative diagrams (Figs. 1 and 2) are also taken :—

Fig. 1.

Fig. 2.

- | | |
|--|------------|
| 11. River sand, humus, &c | Alluvium. |
| 10. Glazy blechne, younger | Diluvium. |
| 9. Older clay, older | |
| 8. Coal-bearing beds | Oligocene. |
| 7. Thick-grained sandstone on the hills, younger | |
| 6. Menilite shales, older | |

- | | | |
|--|---------------------------|-------------|
| 5. Upper Eocene sandstones | Upper | Eocene. |
| 4. Nummulitic sandstones | Lower | |
| 3. Red clays and glassy sandstones | | Cretaceous. |
| 2. Upper Ropienka beds | Upper and Middle (?) | |
| 1. Lower Ropienka beds | (?) The Lower = Neocomian | |

The diagrams exhibit very clearly the manner in which the older beds are, as already pointed out, caused to overlies the newer. They also show that petroleum occurs along the summits of the anticlinal lines, though sometimes wells are preferably drilled where the beds have a regular dip in one direction.

According to Walter, the petroleum-bearing rocks of Lomna and Galowka belong to the lowest strata of the Eocene formation, and therefore resemble those of Bobrka. The strata at Galowka are :—

- 1st. Soft sandstones carrying water; the so-called Kliwa sandstones.
- 2nd. Black bituminous shales, with fish remains.
- 3rd. Horstone and glassy sandstones.
- 4th. A set of blue and red marls, without sandstones, impervious to water.

- 5th. Well-developed sandstones, with thin beds of blue marl. This sandstone is the horizon at which petroleum occurs most abundantly.

A fine series of specimens illustrative of the petroleum and ozokerite deposits of Galicia was exhibited by Professor L. Sajnoch, of Craew, at the International Geological Congress in London (1888). The following examples are extracted from the catalogue of the exhibition :—

Miocene.—Boryskaw, Starunia, Dwiniaez.

Eocene.—Klenczany, Libusza, Lipinki, Wojtowa, Bobrka, Głębokie, Płowce, Zagorz, Łodynia, Pasieczna, Słoboda-Rungurska, Tekucza.

† Das Petroleumgebiet der Galizischen West Karpathen. Wien 1883.

Neocomian (Carpathische Kreide).—Sekowa, Męcina, Siary, Ropianka, Mraznica.

The crude petroleum found in Galicia varies in density and other physical characters within wide limits. The great variation is partly due to the circumstance that oils obtained from relatively deep drilled wells are brought into comparison with petroleum collected in shallow pits. The latter may be described as surface oil, and in many cases it has been so exposed that it has lost its more volatile constituents by evaporation. In some places, *e.g.*, at Siary, Klewa, Rospućie, Starzawa (or Rudawka), Rosochy, and Ropa, a light brown or reddish-brown oil, known as red oil, occurs, which may be burned in ordinary lamps in its crude state,* but the greater part of the Galician crude petroleum is dark brown in colour by transmitted light, and exhibits a marked fluorescence. The oil is usually free from sulphur, and its odour is devoid of disagreeable characteristics. The oil from the drilled wells is very fluid, but the surface oil from the shallow pits is occasionally somewhat viscous.

According to Strippelmann,† the extreme limits of specific gravity recorded are 0.778—0.930 for West Galician oil, and 0.750—0.950 for East Galician. The writer has had occasion to examine from time to time a considerable number of samples of crude petroleum from Galicia, and in the following table, based upon the results obtained, the usual minimum and maximum densities of the produce of the drilled wells are stated:—

TABLE SHOWING DENSITY OF GALICIAN CRUDE PETROLEUM FROM DRILLED WELLS.

	Specific Gravity at 60° F.	
	Lowest.	Highest.
Eastern end of belt: Sloboda-Rungurska	0.830	0.868
Intermediate portion of belt: Ustrzyki district	0.835	0.844
Western end of belt: Wietno district	0.843	0.859

In illustration of a statement already made, it may be pointed out that the oil which was being obtained from the excavated shafts on the Bobrka estate, immediately adjoining the Wietno property, at the time of the writer's visit, had a specific gravity ranging ordinarily from 0.869 to 0.874, and running as high, in exceptional cases, as 0.885.

The extent of variation in the density of the produce of a number of drilled wells in the same locality is shown by the following particulars of properly authenticated samples examined by the writer:—

* This description of oil is also found at Gura Humura in the Bukowina.
† Die Petroleum-Industrie Oesterreich-Deutschlands. Leipzig, 1879.

3	183	8.2	0.841
4	232	5.1	0.836
5	220	10.53	0.841

In making comparisons between the oils obtained from wells at different depths, it should be borne in mind that it is a common practice in Galicia to employ casing perforated at the oil horizons, and that it follows therefore that the produce of a well may consist of oils from two or more petroliferous strata in proportions which are subject to variation.

In the following table some of the results obtained in the writer's laboratory in the examination of several typical samples of Galician crude petroleum are given:—

No.	Locality.	Specific Gravity of Crude Oil.	Specific Gravity of Distillate.					Commercial Products.

It would not improbably be of practical importance, and would certainly be of great interest, if the oils found in the various geological horizons could be differentiated chemically; but it appears doubtful whether this can be done with any degree of precision on the basis of the existent data. At the same time Schaeffer* expresses the opinion that the geologically older petroleum of the Ropianka beds is more limpid and contains a larger proportion of the lighter hydrocarbons than the oils of the Eocene and Oligocene formations, which are comparatively heavy, darker in colour, and are rich in paraffin. While the petroleum of Sloboda-Rungurska contains at most 6 per cent. of paraffin, that of Boryslaw contains 8 or 10 per cent., and that of Starunia as much as 20 to 25 per cent.

Galician petroleum was examined by Lachowicz (Ann. der Chem. 220, 188—206; this Journal, 473). From an oil of boiling point 30° to 125° C. there were separated by distillation and treatment with strong nitric and sulphuric acids, normal and isopentane, normal and isohexane, and normal heptane; also from the higher boiling portions nonane (boiling point 148° C.), and decane (boiling point 152 to 153° C.). An oil boiling between 200° and 300° likewise shows all the properties of the paraffins, a whole series of which form the principal constituents of the petroleum. The first six fractions obtained in the distillation on the large scale of the crude petroleum are not acted upon by bromine, but the seventh and higher fractions absorb bromine vapour with evolution of heat. It is, therefore, most probable that the olefines do not exist in the petroleum, but are formed during the distillation. As it is possible that a formation of aromatic hydrocarbons might similarly take place, only the lightest portions of the distillate were examined with a view of ascertaining the presence of this class of hydrocarbons. By fractionation and nitration meta-dinitrobenzene, dinitrotoluene (melting point 71°), and dinitroxylole (melting point 176°) were severally isolated and analysed, and from a higher boiling portion trinitromesitylene (melting point 231° to 232°). From observations of the high specific gravity and the percentage composition of a portion boiling between 97° and 100° it is, in the opinion of Lachowicz, almost certain that it consists of heptane with some hexahydrotoluene. The presence of hexahydroisoxylene was not proved.

Pawlewski (Ber. 18, 1915; this Journal 4, 671) has isolated paraxylene from the petroleum found at Kleczany. He found that the crude oil contained about 2 per cent. of aromatic hydrocarbons, chiefly benzene and paraxylene. The presence of the latter was detected by brominating the fraction distilling between 125° and 145° C. Crystals of paraxylene bromide, $C_6H_4(C_2H_2Br)_2 = 1:4$, were obtained, melting at 145°.

Nawratil points out that crude oils from the same locality often present considerable differences. Thus of two samples from Kleczany, one from a depth of 189 metres was light coloured and transparent, of low specific gravity (0·779), and yielded light distillates containing much paraffin, while the other, from a depth of 57 metres, was dark coloured and opaque, of high specific gravity (0·870), and yielded heavy distillates containing very little paraffin. Only one of a considerable number of samples examined, viz., that from Pagorzyn, gave off on distillation distinct traces of sulphuretted hydrogen.

As already stated, petroleum was first obtained in Galicia from the pit-wells or carefully timbered shafts excavated by hand. The influx of water and the presence of inflammable gas prevented the sinking of such wells to any considerable depth, and the yield of oil was small. In fact, the more productive petroliferous strata could not thus be reached. The first important step in the development of the industry was taken when hand-drilling was introduced. The plant employed for this purpose is shown in the illustration (Fig. 3), which is taken from a model kindly made for me in Galicia by Mr. Elgin Scott. It consists, as will be seen, of a derrick provided with a powerful windlass A, by means of which a gang of men can draw up the weighty drilling tools B, a smaller windlass or winch C, for use with the sand-pump D, and a long massive beam E (pivoted not far from one end), from which the tools are suspended in the well. The bit or drill F is either chisel-shaped, or more often is of such a form that it may be described as a combination of the chisel and the gouge. It is attached to an apparatus known as the free-fall jars G. This consists of a rod working freely within a casing or tube. The rod is provided with a pin or stud running in a longitudinal slot in the tube, and this slot is prolonged at a right angle at its upper end, forming a catch for the pin. It is obvious that by slightly turning the rod when it is fully telescoped into the tube it may thus be held or released. The tools are attached to the beam through the medium of iron rods H, screwed together, which are added successively as the depth of the well increases. Each windlass is provided with a brake, A', C'. It is usual to commence drilling from the bottom of a square shaft excavated as deep as possible, and the operation consists in drawing down the longer portion of the beam until the end strikes against a wooden block, I. At this instant the driller gives a slight turn to the tools, by means of the lever K, the pin of the jars is released from the catch, and the bit falls a distance of three or four feet, delivering a blow upon the rock at the bottom of the well. The longer end of the beam is then allowed to rise, and the jars thus being telescoped or closed, the driller gives the tools a turn in the reverse direction, and thus again brings the pin into the catch. The beam is usually about 30 ft. in length and pivoted about 5 ft. from one end. A gang of six

* Technologie der Fette und Öle der Fossilien. Leipzig, 1884.

men is required for the work in addition to the driller. Drilling by this method is necessarily very slow, the usual number of strokes which the writer has seen delivered per minute being six or seven. Moreover, the maximum weight of the tools capable of being used with a hand rig is not sufficiently great for expeditious work or deep drilling, and in fact, very hard strata can scarcely be penetrated with such a system. When a bit requires dressing (or sharpening), or the hole is full of detritus, the drilling tools are drawn up into the derrick by means of a wire rope coiled on the larger windlass, the rods being disconnected one by one. The well is then cleared out with the sand-pump D, which is a cylinder provided at the lower end with a valve opening inwards. The sand-pump is lowered into the well by the use of the smaller windlass, and when it reaches the bottom the valve is pushed open by the projecting stem L, and the mud flows in. As the cylinder is raised, the valve, of course, closes.

Fig. 3.

About the year 1867 attempts were first made in Galicia to substitute steam power for manual labour in drilling. The same general arrangement of rig, with free-fall jars, was at first adopted, and is, indeed, still in use to some extent. In one installation which the writer saw in operation in the Sloboda-Rungurska district the piston of the steam cylinder was directly connected with the end of the beam, the tools being suspended from the opposite end, but usually the oscillation of the beam is effected by means of an ordinary steam engine with driving-wheel, the reciprocating motion being given by a crank and connecting rod. The introduction of steam power enabled the driller to use far heavier tools, the weight of the falling portion ranging from 800 to 1,000 kilogrammes, and rendered the work more expeditious, the writer having seen as many as 40 blows of the bit delivered each minute. The free-fall jars employed are shown in Fig. 4 (P P'). While, however, the substitution

of steam power for manual labour in drilling with free-fall jars was the second important step of material consequence in the progress of the industry, a far more important advance was made when the Canadian system was introduced in 1882. Even that system, however, was found to require modification in certain details in order to adapt to the special requirements of the case, the character and disposition of the strata rendering drilling far more difficult as a rule in Galicia than it is in Canada. The derrick and transmission, as well as the principal tools, employed in the Galician modification of the Canadian system are shown in the illustrations (Fig. 1) taken from drawings with which Mr. R. Nelson Boyd has been so good as to furnish me. The derrick is 17·7 metres high, 5 metres square at the bottom, and 1 metre at the top. It is boarded on the outside. The working beam A, is of timber about a foot square. The end of this beam which is over the well is eased with a spirally-grooved cylinder of cast iron, B, carrying the chain supporting the drilling tools. The chain is coiled several times round the cylinder, and then passes to the "slipper out," C, a small winch with ratchet, fixed on the beam. The working beam is caused to oscillate, so that each end has a vertical movement of about a foot, by means of the crank D, and the connecting-rod E. The motive power is a horizontal high-pressure engine F, of about 15 horse-power, specially designed for the work. Steam is supplied from a boiler of the locomotive type. It will be observed that the driller in the derrick can stop, start, or reverse the engine, having control of the throttle-valve in the steam-pipe, through the medium of the "telegraph" or endless cord F', and of the reversing link, by means of the cord F'' attached to the foot lever F'''. The engine also, by means of a belt, drives the windlass G, for drawing up the tools. This belt runs loose when drilling is in progress, and is tightened by the application of a roller, H. A smaller windlass or winch for use with the sand-pump is sometimes employed, and is similarly driven. The larger windlass is provided with a brake, I, which is applied when the tools are being lowered into the well. The slipper-out, the roller for tightening the belt, and the brake are also all under the control of the driller in the derrick, the roller and brake being respectively applied by means of the levers K and L shown in the illustration, and the ratchet of the slipper-out being released by pulling the chain M. A Manilla hemp cable, N, is usually employed in raising the tools, but in many cases recently a wire rope has been adopted, and is found to be far more durable.

The jars O O', as will be seen, differ essentially from the free-fall jars, P P'. There is no arrangement for locking them when telescoped, O and P, and indeed the functions of the two arrangements are quite dissimilar. In drilling with the Canadian jars the whole string of tools and rods, Q, descends, the blow being then struck and the jars R partially closing; as the rods rise the jars at once fully open before the bit S is lifted, and the impact of the two links of the jars on this upward stroke is sometimes of service in dislodging the bit if it has become wedged in the rock. As the drilling progresses, the driller slightly turns the tools, so that the chisel-shaped bit S is caused to make a round hole. The tools are attached to the beam, or rather to the short chain already described, by means of rods, as in the case of hand-drilling and drilling by steam with free-fall jars, but the Canadian rods are of wood (ash). They are 2 in. in diameter, 16 ft. in length, and are connected by conical screw joints T T' with iron straps, U U'. The guide W, shown in the illustration, is an important adjunct to the ordinary Canadian tools which has been adopted in Galicia with a view of preserving the verticality of the well during drilling. It consists of four wings radiating from a common centre, and is inserted in the string of tools above the bit.

As the drilling progresses the well is eased, or lined with iron tubing. A portion of this casing serves to exclude water from the well, but below the water-bearing rocks the casing is necessary to hold up the rock and prevent caving. The difficulties met with in drilling in Galicia are chiefly due to the dislocated character of the strata, and the alternations of hard and soft beds. In some places the strata are disposed nearly vertically, and it will readily be understood that in drilling through soft and friable rock

Fig. 1.

into hard rock at such an angle, the tools are very liable to become deflected, and caving is also very likely to take place. The guides are of great value in keeping the hole

straight, and caving has to be prevented by following the bit closely with the casing. Where the drilling is, in consequence of caving, exceptionally difficult under-reaming

has to be resorted to. This consists in the use of an expanding reamer (Fig. 5) by means of which the well

Fig. 5

may be drilled of the full external diameter of the casing. It is obvious that this could not be accomplished with an ordinary bit, which has to be inserted and worked through the casing, and therefore drills a hole smaller than the inside diameter of the casing. The Canadian drillers, who have had sufficient experience in Galicia, have shown themselves very skilful in the use of the under-reamer, and many wells, which would in all probability have been abandoned, have been successfully completed with the aid of this useful instrument. The rate at which the blows of the chisel are delivered with Canadian tools varies with the character of the ground. Sometimes as many as 70 strokes per minute may be given, but the number usually ranges between 40 and 60.

The under-reamer, which is inserted immediately above the bit, is provided with a pair of pivoted wings or dogs, *a a* (Fig. 5), which are forced outwards into the position shown in B by the pressure of a powerful helical spring enclosed in the tubular rod, exerted through the medium of the sliding collar *b*. When the instrument is to be inserted in the casing this sliding collar is raised as shown in A, and retained in that position by small wedges *c c*. The wings or dogs lie flat against the rod as shown in A. A few strokes of the tools dislodges these wedges, and the dogs at once assume the position shown in B, and "ream" the well to a diameter admitting of the descent of the casing.

The Canadian system of drilling has almost entirely superseded the free-fall system in Galicia. It is undeniably more rapid, and as it is accompanied with far less concussion, the risk of caving is minimised.

With the introduction of appliances for the expeditious drilling of wells by steam power, the original practice of commencing with an excavated shaft has been abandoned,

though in some cases old shafts are made use of where they happen to be advantageously situated. It is usual to case the upper part of the well with what is known as riveted casing. This consists of tubing, made of sheet iron, with riveted seams, and is not water-tight. To shut off the water, artesian casing, consisting of wrought-iron lap-welded tubing, with screwed joints, is employed. The casing is added in successive lengths during the drilling of the well, until it cannot be forced down any lower. The diameter of the well is then reduced, and a smaller casing used. In this way a completed well may have several "strings" of casing in it, each reaching to the surface. It is, however, a common practice to remove some of the artesian casing, taking care to leave that which shuts off the water, but the riveted casing is not withdrawn. In many instances it is found advantageous to use perforated casing below the horizon of the water-bearing rocks, as this, while preventing caving, allows oil to percolate into the well. The small riveted casing with which many wells are completed is not intended to be withdrawn, and therefore extends only up as far as the bottom of the artesian casing. The following particulars of the casing of a well inspected by the writer will perhaps make the foregoing description clearer:—

A.	33 ft. of 13 in. riveted.
B.	65½ ft. of 11 in. artesian.
C.	12½ ft. of 8½ in. artesian.
D.	213 ft. of 6½ in. artesian.
E.	433 ft. of 4½ in. artesian.
F.	236 ft. of 4 in. artesian perforated.
G.	75½ ft. of 3½ in. riveted perforated.

The water was shut off with the 8½-in. casing, and the 6½-in. was withdrawn on the completion of the well. Of the foregoing "strings" of casing, A, B, C, D, and E extended to the top of the well, while F lined the well from the bottom of E for 236 ft., and G completed the lining from the bottom of F for the remaining 75½ ft.

In strata so much inclined, it would doubtless be extremely difficult to drill with a cable in lieu of poles, as is the practice in the United States, but such a serious loss of time is necessarily involved in disconnecting and re-connecting the poles when any great depth is reached, that if an oil-bearing formation lying considerably lower should be found in Galicia, there will be a strong inducement to substitute the cable for the poles.

The following is the approximate cost in Central Galicia of an outfit for drilling by the Canadian system:—

	£
Derrick and transmission	90
Engine and boiler, 15 horse-power.....	250
Drilling and other tools, and pump	410
Poles and belting	200 to 250
Casing	300 to 500
	<hr/> 1,500

The drilling is frequently done by contract at 8s. a foot, the contractor finding labour inside the derrick (a wrench man, a scaffold man, and a third man for odd jobs), while the well-owner provides a smith, a machinist, and a helper, in addition to fuel for the boiler and oil for lubrication and lighting. Labour is cheap and the natives have exhibited considerable aptitude in acquiring the art of drilling, but owing to the number of church holidays it is desirable to adopt labour-saving mechanical appliances as far as possible. In most parts of the oil-fields fuel and water are abundant.

The diamond-boring system has been tried in Galicia, but does not appear to have been successful. The writer saw an uncompleted well in the Sloboda-Rungurska district which had been in process of drilling for over a year and had only reached a depth of 220 metres. In a paper read before the Civil and Mechanical Engineers' Society in 1889, Mr. Nelson Boyd gave some interesting details of the drilling of a well at Polana by the Aqueous Diamond-Boring Company. The power was supplied by a 12 horse-power engine, and the crown was driven at the rate of 120 revolutions per

minute. The quantity of water forced into the hole under a pressure of $1\frac{1}{2}$ atmosphere was 1.52 cubic metre per hour. This was, however, in excess of the necessary quantity, and about one-third of a cubic metre per hour was lost. About 75 per cent. of the water requisite may be saved, so that the actual consumption would be about half a cubic metre per hour. At a depth of 200 metres the drawing of the rods, the removal of the core, and the lowering of the crown again, occupied two hours, and this had to be done for every 10 feet of boring. In shale, as much as 2.7 metres were bored in an hour, and in sandstone 0.828 metre. Mr. Nelson Boyd considers that the results obtained in this well were of a favourable character, but he points out that the inclination of the strata constitutes a great impediment to the use of the diamond drill in Galicia, as the upper part of the stratum perforated is liable to slide on a joint and jam the core.

The rate of drilling in the Ustrzyki district commonly ranges from 12 to 18 up to as much as 50 or 60 ft. in 12 hours, according to the hardness of the strata. Not infrequently considerable delay is caused by the breakage of the tools, and some of the resulting "fishing" operations demand much skill and patience, but it is very seldom that a well has to be abandoned in consequence of such an accident. The depth of the wells in the Ustrzyki district is commonly from 220 to 250 metres, the first indications of oil being met with at a depth of 30 metres, the first oil horizon being perforated at 120 metres (the well then yielding from $\frac{1}{4}$ to 1 barrel a day), and the second oil horizon at 160 to 220 metres. It is believed that a third and probably more productive oil horizon may exist at a greater depth in this district, but the wells are not drilled below the second, when they usually yield about 20 barrels of oil per diem but sometimes much more.

In the Sloboda-Rungurska field the depth of the wells usually ranges from 215 to 330 metres, but in some instances exceeds 400 metres. The following particulars of the strata met with in the drilling of a well to a depth of 245 metres in this district are given by Babu:—

	Metres.
Green and red shales alternating.....	85.00
Unimportant beds of shale and sandstone, alternating	35.00
Hard shale.....	13.75
Hard sandstone (1st petroleum horizon).....	15.00
Shale.....	2.50
Hard sandstone.....	10.25
Alternate layers, 1 to 10 metres in thickness, of sandstone and marl.....	51.87
Sandstone (2nd and more important petroleum horizon).....	41.38

The writer was informed that the average time occupied in the drilling of a well in this district is three months, but he saw a well there, stated to be flowing at the rate of 70 to 80 barrels per day, which was drilled to a depth of 220 metres, with a diameter of 6 inches at the bottom, in 18 days. About 25 per cent. of the wells drilled in this district have been unproductive and the yield of the remainder appears to have varied considerably. Many of the wells flow at first and afterwards need pumping. One produced for a time as much as 300 barrels per diem, and afterwards for a year an average of 200 barrels a day. The smallest yield for which it is considered profitable to pump in this district is two barrels a day.

In the Wietzno field the writer saw a well out of which oil was flowing simultaneously from two horizons, through the 5-in. and 6-in. casings, respectively. The estimated yield of this well was 200 barrels a day. The depth of the wells in this field is about 250 metres. In the historic Bobrka field there were at the time of the writer's visit some 30 wells being pumped, some of which had yielded small quantities of oil for 17 or 18 years, but the ordinary life of a drilled well in Galicia is perhaps one-third of this period. The usual experience has been that provided a distance of 20 metres intervenes, one well does not drain another. The deepest drilled well in the Bobrka field at this time had a depth of 409 metres and a diameter of 6 in. at the bottom, while the deepest excavated shaft on the property had been carried down to 154 metres, with a uniform diameter of one metre.

The pumps used in raising oil from those wells which do not flow are of small diameter (1 to $1\frac{1}{2}$ in.), and are furnished with double or triple buckets with ball valves. The working barrel is placed at the bottom of the well, and $\frac{1}{2}$ -in. gas piping is frequently used as a sucker rod. To economise steam power a number of pumps are worked from one engine through the medium of rods, the power being thus sometimes transmitted a considerable distance.

The oil is conveyed to the refineries partly by barrels by road, and partly in tank-waggons by rail. In some cases short pipe-lines have been laid down from the wells to the railway to facilitate transportation. The railway rates for transport are moderate and the companies possess tank-waggons.

The drilling leases in Galicia are commonly for a period of 25 years, the lessee making a cash payment for the lease of an amount depending upon the character of the territory, and obtaining the usual rights of ingress and egress, the agricultural rights remaining with the lessor. The royalty payable by the lessee ranges from $12\frac{1}{2}$ per cent. to as much as $37\frac{1}{2}$ per cent. of the oil raised, and the lessee also pays a small rent for the land actually occupied by him. The system of land registration admits of drilling rights over oil-lands being intabulated in the land books, and thus affords to the petroleum producer perfect security at a trifling cost.

In the following table the production (in metre centners)* of the petroleum properties in the localities specified for 1889—90 (12 months) is given, and on referring to the series of three maps (Maps Nos. 2, 3, and 4) in which these localities are marked, a good idea of the extent of the oil-belt, as far as it has been demarcated, will be obtained. It will be observed that notwithstanding the large amount of work which has been done, an immense area of presumably oil-bearing territory remains undeveloped.

NOTE.—The production in the neighbourhood of Krosno commenced too recently to find a place in the foregoing table.

In the following tabular statement the quantities of crude petroleum produced in and imported into the kingdom of Austria-Hungary during the years 1883—90 are given. The figures demonstrate that the local production must be very largely increased before it overtakes a consumption which is still growing:—

	Production of Austria-Hungary.	Imported into Austria-Hungary.	Consumption.
	Barrels.	Barrels.	Barrels.
1883	106,500	735,000	904,500
1884	233,000	899,735	1,132,735
1885	333,000	937,345	1,270,345
1886	433,000	858,976	1,291,976
1887	532,000	388,110	920,110
1888	665,000	801,715	1,466,715
1889	746,000	930,191	1,676,191
1890	816,000	867,831	1,683,831

The figures given in the foregoing tables are taken from official sources, but in the opinion of those best qualified to judge, the quantities are largely understated.

The present average price of the crude oil is 3 fl. 45 kr. per 100 kilos, equal to about 8s. per barrel.

At the Peezenyzen refinery in the Kolomea district, which the writer visited in 1887, the crude petroleum is distilled in horizontal cylindrical stills, the lower plates of which are of steel and the upper of iron. These stills take a charge of 200 barrels and 12 charges a month are worked off. In this operation only the benzine and kerosene are distilled off, and a portion of the residuum thus obtained is used as fuel for the stills, being burned partly with a steam-jet spray-producer, and partly in admixture with sawdust. The kerosene distillate is treated with 3 to 4 per cent. of sulphuric acid in lead-lined agitators holding 500 barrels. The crude oil, which is obtained from the neighbouring Sloboda-Rungurska field, is stated to yield from 4 to 8 per cent. of benzine (according to the length of time that it has been above ground), 58 per cent. of "standard oil" (sp. gr. 0·813 to 0·816, and flashing point 22° C.), 4 per cent. of "inflammable oil," and 2½ to 2¾ per cent. of solid paraffin. The paraffin oil, which is distilled from the residuum of the kerosene stills in small (40 barrel) stills with steel bottoms, is "chilled" by mixing it with crushed ice, and the paraffin is obtained by subjecting the semi-solid mass to pressure in Canadian presses, which are wooden lever presses of simple construction. Lubricating oils were not manufactured at this refinery, which is the largest in Galicia, at the time of the writer's visit. At a small refinery in Ustrzyki, which

he inspected, the crude oil is distilled in wrought-iron pot-shaped stills, 6 ft. in diameter and 5 ft. in height, the condensers being worms of 3-in. iron pipe. At this refinery various classes of crude oil were then being distilled, and the percentage of products obtained was as follows:—

	Wietzno Crude.	Ropienka Crude.	Polana Crude.
	Per Cent.	Per Cent.	Per Cent.
Benzine	15	10	5
"Saloon oil"....	30	35	40
2nd grade oil....	8 to 10	10	15

The residuum is further distilled in the same stills, and yields about 20 per cent. of heavy oil, which is redistilled. The final residue usually amounts to about 10 per cent., and the loss to about the same percentage. It appears to be customary to mix the second grade of kerosene with benzine, and a burning oil is thus obtained which is inflammable at common temperatures, but is nevertheless used locally as a lamp oil to a considerable extent. Galicia would appear to offer a very promising field for the employment of a dissociation process of distillation, whereby the yield of kerosene might be largely increased.

The petroleum industry in Austria-Hungary is a protected one, an import duty of 10 florins (gold) per 100 kilos, on refined oil (kerosene) and 2.40 florins (gold) on crude petroleum being levied. An exception is made in the case

of Roumanian crude petroleum, which is admitted on payment of 68 kr. per 100 kilos. Of this crude petroleum 164,333 metre-centners (109,555 barrels) were imported in 1889, and 155,901 metre-centners (103,934 barrels) in 1890.

Notwithstanding the encouragement thus given to the native industry, the consumption is, as already shown, very largely in excess of the aggregate quantity of petroleum produced in the Monarchy. The deficiency is supplied by the Russian petroleum imported into and refined at Fiume. This petroleum, though nominally crude oil, is understood to contain very far more than the natural percentage of kerosene, and considerable dissatisfaction has been manifested by the Galician refiners at what is regarded as an evasion of the fiscal regulations. The important position which the Fiume refinery occupies in relation to the industry as a whole is made evident by the following table giving the declared value in Austrian florins of the refined petroleum manufactured at the various refineries in Austria-Hungary for the years 1886—89. The table is based upon particulars supplied by the Finance Minister, and may therefore be accepted as an official statement, but it is generally believed that the declared values are very largely understated. It is thus difficult to estimate even approximately the consumption of petroleum in Austria-Hungary; some authorities being of opinion that the figures given might in many cases, at any rate, be doubled. The accompanying map (No. 5) which has been drawn for this paper, exhibits more clearly the distribution of the petroleum-refining capacity of the Monarchy, and the output of the various refineries.

TABLE showing the DECLARED VALUE, in AUSTRIAN FLORINS, of the REFINED PETROLEUM Manufactured at the Various REFINERIES in AUSTRIA-HUNGARY, for the Years 1886—89.

Based on particulars supplied by the Finance Minister.

These statistics show, therefore, for the year 1889 as compared with 1888, an increase of 327,153 fl. = 27,262*l.* 18*s.* 4*d.* sterling, and as compared with 1887, 1,565,955 fl. = 132,996*l.* 10*s.* sterling, while as compared with 1886 the increase amounts to 2,219,713 fl. = 184,976*l.* 1*s.* 8*d.* sterling.

II.—Ozokerite.

The principal seat of the ozokerite mining industry is at Boryslaw, where the extraction of the mineral has afforded occupation to a large number of men and women during the past 30 years.

Boryslaw is a town of 20,000 inhabitants lying in a valley surrounded by hills at the foot and on the northern slope of the Carpathians, 12 kilometres south-west of Drohobicz.

It is 360 metres above sea-level, and is traversed by a small river. One kilometre to the east of it is Wolanka.

Ozokerite is mined to a small extent in Dwiniacz and Starunia, which lie to the south of Stanislaw. It also occurs at Truskaviec and Tustanowiec, near Boryslaw, at Slanik in Moldavia, and in many other places on both sides of the Carpathians. The mineral is also found in quantity in the islands of Teheleken and Swjatoi in the Caspian Sea, and has been met with on the Transcaspian mainland as

well as in the Kouban. Recently it has been obtained in commercial quantities from the Wasatch mountains, 113 miles east of Salt Lake City, Utah.

The following are localities where ozokerite is reported to occur:—

England—Newcastle.

Galicia, Roumania (near Plojesti and Slauik), Hungary, and elsewhere.

Wettin-on-Saal, East Frisia.

Derbent (near), Baku, Islands of Tchelen and Swjatoi, Ekaterinodar, Station of Kalochinsky, Transcaucasia.

Egypt.

Utah, Texas, Arizona, Oregon, Canada, Manitoulin Island.

It is difficult to say whether ozokerite is peculiar to any particular geological formation. Regarding it as a description of petroleum with a high melting point, Râteau points out that it would not be reasonable to expect that it would be confined to any one formation, and, in fact, it is found in many, though chiefly in the Tertiary and Cretaceous. The Boryslaw, Dwinaez, and Starunia deposits are in Miocene, but ozokerite has been met with in the shales of Teschen, as well as in Neocomian and other formations elsewhere. The Kouban deposits are on the borders of the Lower Tertiary and Upper Cretaceous. In Tchelen it is found accompanying petroleum in pockets in beds of sand above the clay-shales and muschelkalk of the Aralo-Carpathian formation. In Southern Utah and Arizona it occurs in Tertiary rock, probably Miocene. Rock salt and gypsum are commonly found in association with the ozokerite in Galicia. Occasionally these minerals occur in an almost pure state, but they are more frequently mixed with clay. At Boryslaw salt and gypsum are often found in the ozokerite. At Truskawice, near Boryslaw, there is a deposit of native sulphur and sulphides, intermingled with gypsum, ozokerite, and petroleum. The formation here is a greyish-blue clay-shale, with sand and marl. The association of petroleum and rock-salt is not peculiar to Austria-Hungary, and may be said to be a frequent characteristic of oil-producing districts. In some of the Carpathian salt-beds no liquid or solid petroleum is met with, but large quantities of gaseous hydrocarbons are evolved. Carbonic acid and sulphurous acid, as well as sulphuretted hydrogen, are also given off, and frequently under great pressure.

The soil of the valley in which Boryslaw lies is a bed of diluvial deposit some metres in thickness. In sinking a shaft, first yellow clay, then rounded flints and gravel, and then plastic clay are met with. Below this, sandstone and blue shale, much disturbed, alternate, and it is in these beds, which have a thickness of some 200 metres, that the ozokerite is found. The ozokerite-bearing formation, which is considered to be of Miocene age, lies on a basis of petroliferous menilite shale, the strata of which, as they approach the surface, are disposed almost vertically, but inclined towards the south. This structure, which bears evidence of the complete disruption which the rocks have undergone, is shown in the accompanying section by Paul (Fig. 6). The strata are composed of layers of coarse-grained

Fig. 6.

sandstone, green marl, fine-grained sandstone with veins of calcite, dark shale alternating with grey sandy shale, imperceptibly merging into the main beds of the non-petroliferous sandstone and shale. Below these are the Carpathian sandstones of the lower Eocene (nummulite sandstone) and Upper Cretaceous formations. It should be pointed out that the basin of menilite shale and the beds of shale and sandstone are disturbed by a fault, the Miocene rocks having thus become mixed with the Carpathian sandstone, and it seems reasonable to conclude

that the petroleum and ozokerite may have found their way into the Miocene formation through this fault, for without this means of escape the hydrocarbons would have been imprisoned by the beds of shale lying between the Carpathian sandstone and the menilite shale. A consideration of this view led M. Râteau to express the belief that by drilling to a depth of 400 or 500 metres large quantities of petroleum might be obtained in this neighbourhood from the lower Carpathian sandstone layers. The geological conditions prevailing at Dwinaez and Starunia are similar, but the ozokerite is more largely mixed with petroleum. The soil is grey and red diluvial clay, below which is a bed of gravel, lying on the Miocene formation in which the ozokerite and petroleum occur in association with native sulphur, iron pyrites and zinc blende. Still lower a highly porous calcareous rock is met with, containing cavities filled with petroleum and sulphuretted water, and below this again is a marl with gypsum and the salt-clay formation destitute of petroleum.

The ozokerite occurs in the form of veins of a thickness ranging from a few millimetres to some feet, and is accompanied with more or less petroleum and gaseous hydrocarbons. It fills the many fissures with which the disturbed shales and Miocene sandstone abound, and frequently forms thus a kind of network. The Boryslaw deposit extends over a pear-shaped area, the axis of which lies E. 30° S. The town of Boryslaw lies on the broader portion of this area and Wolanka at the point of it. The upper layers of the richest portion of the deposit occupy an area of about 21 hectares, with a length of 1,000 metres and a maximum breadth of 350 metres, but outside this there is an outer zone of less productive territory which increases the total superficies to about 60 hectares, with dimensions of 1,500 metres by 560 metres. The deposit narrows considerably as the depth increases, and at a distance of 100 metres from the surface of the ground has a breadth of only 200 metres. This is held to indicate that the deposit has found its way upwards from some very lying formation (probably through the fault already referred to) and has gradually extended itself laterally through the interstices in the disturbed rocks as it neared the surface. The ozokerite-bearing formation contains also much petroleum, and is bordered on the south-east and west by petroliferous territory.

It has been pointed out by Babu that the study of the geological occurrence of ozokerite may be of considerable assistance in forming conclusions in regard to the geology of petroleum, for the deposits of ozokerite may be followed up as readily as a vein of metal. On the other hand, ozokerite does not indicate its presence by rising to the surface of the ground as petroleum so often does.

The name of ozokerite is derived from *ὄζω* = to smell, and *κνίψ* = wax. It is usually spelt without the final "e" by German authors, and that form has been adopted by Messrs. J. C. and J. Field, who are so prominently identified with the industry. It will probably be in accordance with usual practice to retain the final "e" in the case of the mineral and drop it in spelling the name of the distilled product. The mineral, which is commonly known in Germany as *erdwachs*, also bears, according to Schaedler, the following designations:—*Bergwachs*, *fossiles paraffin*, *fossiles wachs*, *kenderbal*, *lehmnapththa*, *mineralwachs*, *steintalg* (mineral tallow), *cire de terre*, *neft-gil* (Persian), *nefta ghil* (Turkish).

Ozokerite varies from a very soft material, which may be regarded as a petroleum very rich in paraffin, to a black substance as hard as gypsum. The density of ozokerite ranges from 0.850 to 0.950, and its melting point from 58° to 100° C. It is soluble in benzol, oil of turpentine, and petroleum. It is a good insulator, and has been recommended for use as such in admixture with 50 per cent. of india-rubber. Ordinary commercial Galician ozokerite, such as is employed in the manufacture of *ceresin*, has the following properties:—It is soft and plastic, and has a very fibrous fracture. The colour varies from light yellow to dark brown, and it frequently has a greenish hue owing to dichroism. It becomes negatively electrical by friction and exhales an aromatic odour. It becomes more plastic on heating, and usually melts at about 62° C.

According to Laeh (Chem. Zeit. **13**, 831; this Journal, **8**, 696), Caucasian ozokerite is inferior to Galician. Its melting point is 68°C , and on treatment with 20 per cent. of fuming sulphuric acid it yields 58 per cent. of second quality ceresin of melting point 68.5°C .

A material described as ozokerite is found in Colorado. It is a dull black substance, hard and pulverisable, with a melting point of 76°C . It does not yield ceresin, but on being subjected to distillation it furnishes the following results:—

	Percentage (by difference).
Paraffin and oil.....	90.00
Loss in gas.....	2.12
Loss in water.....	2.60
Residue.....	5.28

It commences to distil at 360°C , when nearly 3 per cent. of oil setting at 30°C comes over. At a much higher temperature it distils steadily and furnishes a product suitable for use as a source of paraffin.

The following are particulars of samples of ozokerite from various sources:—

BAKU.—Specific gravity 0.903, melting point 79°C .

	Per Cent.
Paraffin mass.....	81.8
Gas.....	13.8
Coke.....	4.4
	100.00

Heavy oil, with paraffin, 150° to 300°C	35.10
Paraffin, &c., over 500°C	49.73
Residue in retort, and loss.....	8.92
	100.00

—Josef Merz.

Ozokerite consists of a mixture of hydrocarbons in various proportions. It contains 85.7 per cent. carbon and 14.3 per cent. hydrogen.

According to R. Hegor (Seifensied. Zeit. **321**; this Journal, **2**, 473), the composition of ozokerite may be best represented by the formula $\text{C}_{20}\text{H}_{32}$. It appears to have been formed by the oxidation and decomposition of the hydrocarbons of naphtha, since the action of oxygen on these compounds simply eliminates hydrogen. Thus, for example, naphthalene gives dinaphthyl and water—

By further oxidation there are obtained compounds of the formula C_nH_{2n} , which react with the hydrocarbons of the marsh-gas series, with formation of very complex carbon compounds of various melting points, as for example:—

Zaloziecki (Zeits. f. angew. Chem. **1888**, 261—263; this Journal, **7**, 428) has separated crystalline paraffin from refined ozokerite (ceresin) by the use of warm methyl alcohol as a solvent. After pressure and repeated crystallisations from methyl alcohol, a product was obtained which upon fusion and subsequent cooling formed a translucent and distinctly crystalline material closely resembling paraffin in its properties. The substance separated by the first solution in the alcohol was soft and pasty, and had a melting point of 32° – 33° , while the melting point of the ceresin was 65° . The natural inference is that in addition to crystalline paraffin ozokerite contains certain colloidal substances (amorphous paraffin), the presence of which hinders the crystallisation of the paraffin. These substances are removed by the methyl alcohol in consequence of their greater solubility, and doubtless become either converted or decomposed in the process of distillation ordinarily adopted in the manufacture of crystalline paraffin from ozokerite.

F. Redl (Chem. Zeit. **11**, 415—416; this Journal, **6**, 504) purifies ozokerite by heating it to 120° to remove water and light oils and then allowing it to cool to 75° , when it is treated with 50 per cent. of naphtha of sp. gr. 0.700 – 0.720 . The mixture is gently agitated, and 10 per cent. of fuming sulphuric acid added. After further agitation, subsidence is allowed to take place during 20 minutes, and the ozokerite at a temperature of 70° is treated with caustic soda solution, after which the naphtha is removed by distillation. The decolourisation of the ozokerite is completed by means of charcoal.

Zaloziecki (Dingl. Polyt. J. **265**, 178—184) refers to the well known fact that the yield of ceresin is largely affected by the purification of the ozokerite with sulphuric acid, from 15 to 30 per cent. being lost during this operation. He finds that the loss is, if anything, smaller at a temperature of 200° than at 160° , which he accounts for by assuming that at the higher temperature the sulphuric compounds are decomposed with the regeneration of sulphurous anhydride and hydrocarbons.

In mining the ozokerite it is usual to sink a circular well 3 metres in diameter through the upper beds of clay until the water level in the gravel is reached. This well may have a depth of 14 to 16 metres. In the centre of it a shaft 1.3 metre square is built up of balks of timber jointed together, the intervening space being filled with clay. The digging and timbering of a shaft 1.3 metre square is then continued until further progress is arrested by inflammable gas or water. When this occurs, one of the veins of ozokerite intersected by the shaft is opened up and followed by means of a timbered gallery. Immense pressure is exerted by the semi-fluid ozokerite, and it is usual to employ timbers not far short of a foot square placed not more than one metre apart. The writer has seen timbers of this size which had been broken like matchwood by the pressure to which they had been subjected in the galleries. Sometimes the ozokerite suddenly bursts into the workings and overwhelms the miners, and there are cases on record of men having been unexpectedly raised from the bottom of the shaft to the surface of the ground by an influx of the semi-fluid mineral. One shaft was pointed out to the writer as bearing the name of the Asparagus shaft, from the

circumstance that on a thin layer of sandstone which was met with at a depth of 160 metres being perforated by the miner's pick, the underlying soft ozokerite was slowly forced up through the opening in a form which resembled the vegetable specified, the "growth" being for a long time renewed as often as it was removed.

The horizontal galleries cannot without serious danger be driven to any considerable distance, not in fact beyond about 5 metres, but driving much further, even if free from risk, would not be possible in most cases owing to the contiguity of the properties. As it is, frequent quarrels ensue in respect to the underground rights. The disused galleries are usually allowed to fall in, but are sometimes filled up. The water and oil which occur with the ozokerite are drawn off from the bottom of the shaft. The sinking of the circular well costs about 4 fl. the metre, but in the dislocated beds below, where the ozokerite is met with, the cost of sinking is from 5 to 10 fl. the metre run, without reckoning the cost of pumping out the water. The driving of the galleries is paid for at the rate of 7.50 fl. to 9 fl. per metre run. The shafts and galleries are, however, more commonly excavated by contract, the price per metre for the former down to a depth of 130 metres being from 20 to 25 fl., and for the latter 5 to 8 fl., both without timbering. This brings the cost of a shaft of 100 metres, inclusive of timbering, to 2,000—4,000 fl., or for a shaft of 200 to 225 metres, 10,000—12,500 fl.

Over the mouth of the shaft is fixed a windlass carrying a wire rope, to each extremity of which is attached a bucket used in drawing up the ozokerite and in lowering and raising the miners. The descent is made by placing one foot in the bucket and holding on to the rope, the other foot being used in fending the bucket off the sides of the shaft. Owing to the subsidence and lateral movement of the earth due to the extraction of the ozokerite the shafts do not long remain vertical, so that the descent is not a pleasant experience. The miner wears a safety belt to which a rope is attached, which passes over a smaller windlass. Much inflammable gas is met with in the workings, and safety-lamps are necessarily used. Ventilation is unsatisfactorily effected by means of a revolving fan turned by a woman. Within easy reach of the miner in the gallery is a cord communicating with a bell at the mouth of the shaft, by means of which he can summon assistance; but notwithstanding the provision of the bell and the safety-belt, deaths from suffocation are not uncommon. The inhalation of the gas appears to produce a kind of intoxication, which some of the miners find enjoyable. The underground miners receive 0.75 to 1.25 fl. per day, while the labourers employed above ground get about 0.60 fl. The majority of the people employed are of a low class, and they usually work on the basis of a daily contract. Heurteau states that in 1871 of the 10,000 workmen engaged in the industry, 2,000 were underground miners, and among these there were usually from 200 to 300 accidents per annum, nearly all fatal. In some years there are said to have been as many as 1,000 deaths due to such accidents. According to Rateau, the "admitted" annual death-rate due to accidents ranges from 7 to 15 per 1,000 (compared with 1.88 per 1,000 in "ordinary mining"), but he adds that the rate is understated. It will doubtless be evident to most visitors to Boryslaw, that notwithstanding the salutary effect of a code of regulations which are supposed to be enforced by officials specially charged with the duty, much of the underground work is carried on under unnecessarily dangerous conditions. The staff of officials consists of an inspector, a cashier, a geometriean, three overlookers, and six or eight police agents. To defray the expenses of this superintendence a charge of two florins per shaft is levied on the proprietors. The very primitive character of the arrangements adopted is well shown in the illustration (Fig. 7), which is taken from an interesting model made in Galicia, and kindly presented to the writer, together with a number of specimens of the crude ozokerite and various commercial products, by Mr. Wentworth Sturgeon.

The unscientific method in which so important an industry continues to be conducted may excite surprise, but it should be borne in mind that the right of raising petroleum and

ozokerite belongs to the surface owners of the land, the result being that there are in Boryslaw a number of small landed proprietors, who, with the assistance of their wives and children, raise as best they can the petroleum and ozokerite lying beneath their plot of ground. It is not surprising that work of an admittedly difficult and dangerous character conducted thus with insufficient capital, inadequate appliances, imperfect organisation, and lack of skill should have been attended with much unnecessary loss of life, especially when the reckless character of the population is taken into account. Attempts have been made to place the industry upon a proper basis, and a French company was some years ago formed with the object of extracting the ozokerite by the adoption of a systematised scheme of mining, but the shafts sunk by this company were unfortunately not favourably situated for the successful carrying out of the project. It would undoubtedly be very beneficial if some fusion of interests could be effected, so that the industry might be placed on a more satisfactory footing.

Distributed over an area of 90 to 100 hectares are many thousand shafts, ranging in depth from 20 to 200 metres, but the writer was informed that not more than 400 of these were being worked when he visited Boryslaw. The shafts are in many cases not more than from 3 to 8 metres apart, and the available surface ground round each shaft usually ranges from 9 to 60 square metres. When it is considered that there are hundreds of separate proprietors it will be understood that there is frequently considerable confusion, and that there is great difficulty in getting rid of the earth excavated and raised with the ozokerite. It has been the practice to shoot the material between the houses or on any vacant piece of ground and naturally as near to the wells as possible. The result is that the whole place is deeply covered with an oily mud, through which it is difficult to make one's way. Recently arrangements have been made for the systematic removal of the débris.

As already stated, a French company has carried out the system of mining for ozokerite by means of a well-constructed shaft and carefully-timbered galleries, such as are adopted in coal-mining. The diameter of the main shaft through which the ozokerite is raised is 2 metres, and there is a smaller shaft, 1.50 metre in diameter, through which the water is pumped. The mine being situated near Wolanka and to a large extent outside the zone of the most productive territory, the system can scarcely be said to have been fairly tested. In this outer zone there is not only less ozokerite, but there appears also to be much more water to be contended with. The main shaft is fitted with cages running in guides and operated by a steam engine. Ventilation is effected by means of centrifugal exhausters, also driven by steam power.

The ozokerite occurs sometimes in sheets as thin as paper, but more often in veins from 2 or 3 in. to a foot in thickness disposed in the most irregular manner. The mineral is broken out by hand with the pick and wedge, and this may be regarded as easy work owing to the disturbed character of the strata in which it occurs.

For the working of each shaft two miners, two labourers, and one woman are needed. The annual cost of this labour is 1,000 to 1,500 fl., and other charges, with interest on capital, bring up the total working expenses, according to Babn, to 3,500 to 4,000 fl. per shaft. Taking the produce of each shaft at 15 to 18 tons on the average the cost of the ozokerite to the proprietor would be from 16 to 18 fl. per 100 kilos. Presumably this is the cost of mining the mineral within the inner zone.

An attempt has been made to estimate the quantity of ozokerite in the Boryslaw deposits. The basis of the calculation is that the outer zone demarcates a territory containing 2 per cent. of the mineral, while the proportion in the inner zone is more than 5 per cent. Taking the dimensions of the zones already given and further assuming the extraction of the deposits to a maximum depth of 200 metres, the total quantity of ozokerite obtainable would be more than two million tons.

Two products are obtained from the mines, viz., nearly pure ozokerite in fragments, and earth containing much

ozokerite. The former is melted as it is, while the latter is subjected to the following operations in consecutive order;—

1. Hand picking or sorting.
2. Washing with cold water.
3. Washing with hot water.
5. Treatment with benzine and steam.

By hand picking all the larger fragments of ozokerite are sorted from the earthy matter. The work is performed at the pit's mouth by women, who are provided with a small mattock by means of which the separation of the matrix is facilitated. After this the earth, which still contains from 8 to 10 per cent. of ozokerite, is thrown into tubs of water and stirred with shovels. Under these circumstances the liberated ozokerite rises to the surface and is skimmed off with a sieve. The earth, still containing from 4 to 5 per cent. of ozokerite, is then subjected to the action of boiling water and the finer particles of the wax, aggregated by fusion, rise to the surface in the form of a black oily semi, which is removed from time to time. The fourth process, originally suggested by Van Haeht, consists in exposing the earth which, after treatment with boiling water, still contains from 1 to $1\frac{1}{2}$ per cent. of ozokerite, to the solvent action of benzine. By this means nearly the whole of the remaining wax is dissolved, and by steam distillation the benzine is recovered. The ozokerite thus obtained commands a higher price than which is obtained by either of the three preceding processes.

The separated ozokerite is melted and cast into loaves or blocks of the form of a truncated cone, and weighing about 50 or 60 kilos. One of these blocks is on the table. The expenses of picking, washing, and melting amount to from 40 to 50 krentzers per quintal.

There are two or three recognised commercial qualities of the melted and cast ozokerite. The first quality is transparent in thin sheets and its colour ranges from yellow to greenish brown. Adulteration by means of crude petroleum, heavy oils, the residues from refineries, asphaltum, and even earthy matter, are not unknown, and occasionally by a process of double casting the exterior of the block is made to differ in quality from the interior.

In the form of the blocks described the ozokerite is delivered to the Austro-Hungarian refineries, and exported to Russia, Germany, and England. The principal refineries are in Drohobicz, Lemberg, Vienna, Stockerau (near Vienna), Aussig, Teplitz, Elbeteinitz, London, Halle, Frankfort, and Hamburg.

In the following table the quantity and price of the ozokerite raised in Austria-Hungary are given for the years 1877—90. The figures are official, but, as in the case of petroleum, the production is probably very largely understated. The greater part of this ozokerite is the produce of the mines of Boryslaw, but a portion was obtained from the deposits at Truskawice, Starunia, and Dwiniacz.

The raw material, which has been separated from earthy matter by fusion, is treated with Nordhansen oil of vitriol, whereby a portion of the material becomes converted into a soluble sulpho-compound, and afterwards with charcoal.* The purified ozokerite, which then bears the name of ceresin, is separated as far as possible from the charcoal by pressure, and an additional quantity is obtained by exhausting the charcoal with benzine, which is afterwards distilled off. There is thus usually obtained from the crude ozokerite from 60 to 70 per cent., or even more, of ceresin, which in some cases is afterwards coloured to imitate beeswax, and is largely used on the Continent, especially in Russia, as an adulterant of, or even as a substitute for that material, especially in the manufacture of church candles. Refined ozokerite or ceresin usually ranges in melting point from 61° to 78° C., but notwithstanding its high melting point, when made into candles, it exhibits a tendency to gutter; it also burns with a smoky flame. For the production of the material of which candles are made, the ozokerite is subjected by Messrs. J. C. and J. Field, Limited, to a process of distillation, patented in 1870 by Field and Siemens. Under this process the ozokerite is

melted, pumped into stills, and distilled in a current of superheated steam.† The distillate is eaked, pressed with naphtha, cleared down with Fuller's earth, and filtered. Under favourable circumstances, with good material, about 60 per cent. of white wax, of a melting point of 140° F., may thus be obtained. Candles made of this wax are especially adapted for use in high temperatures, as they are less liable to gutter and bend than ordinary paraffin candles. In addition to light oils, the crude ozokerite yields under certain circumstances a semi-solid product resembling vaseline, but less homogeneous. This product, known as yellow ozokerine, is used in ointments and pomades. By the action of Nordhansen sulphuric acid it is rendered white, and in that form is employed by French perfumers as a substitute for lard in the process of "enfleurage," the almost entire insolubility of the hydrocarbon in alcohol, and its non-liability to become rancid, giving it a great advantage over the animal fat.

The residue in the stills consists of a hard, black, waxy substance, for which at first no use could be found, but in 1875 Messrs. Field and Talling took out a patent for producing electrical insulating material by combining this black ozokerite with india-rubber by welding through rollers at a moderate temperature, and subsequently vulcanising the compound. This material, with certain modifications, has been introduced as "okonite," and is now largely used by the Okonite Company for the insulation of electrical cables. Okonite is not only a good insulator, but is remarkably flexible and tough. By a similar process a form of the material known as heelball is manufactured. This is employed to impart a black polished surface to the heels and soles of boots; it is also very largely used by the Austrian Government for the leather work of cavalry and artillery. The consumption of the black ozokerite in consequence of these industrial applications of what was at first a valueless by-product has now become so great that the present demand largely exceeds the supply.

For the very complete and highly interesting series of illustrative specimens, as well as for much valuable information relative to the ozokerite industry, the writer is greatly indebted to Mr. Leopold Field, who is well known to have devoted special attention to the technology of the subject. The specimens include natural ozokerite from a large seam

* The carbonaceous residue produced in the manufacture of potassium ferrocyanide being employed.

† If the ozokerite is subjected to destructive distillation, it is very largely converted into gas, oil, and coke, but in the presence of superheated steam this decomposition does not take place to any important extent.

at a depth of about 350 feet (such ozokerite yields by the system of distillation adopted by Messrs. Field about 60 per cent. of white ozokerite (melting point 140° F.) 30 per cent. of black ozokerite and 3 per cent. of ozokerine, the remaining 7 per cent. being represented by gas, light oil, and coke) crude ozokerite ("primitiva") as imported, showing the characteristic fracture and dichroism of the material; distilled ozokerite, 140° F. melting point, ozokerite candles and nightlights; black ozokerite, "okonite" and heelballs; "ozokerine," yellow and white; eeresin.

For the specimens of electric cables insulated with okonite, the thanks of the writer are due to the Okonite Company.

In conclusion, the writer cannot too strongly express his indebtedness to Mr. George Adams, whose long experience and intimate knowledge of the industry have been generously placed at his disposal, and have been of the greatest value to him in the preparation of this paper. The writer's cordial thanks are also due to Imperial and Royal Commissioner Henryk Walter, of Cracow, who has kindly furnished him with much valuable statistical information.

DISCUSSION.

Mr. W. TORLEY, F.R.S., ventured to assert that no one would in future attempt to discuss or write about the petroleum and ozokerite industry of Galicia without referring to this paper. He thought Mr. Redwood had dealt with the subject in a very masterly manner. What he had to say would be mainly geological. Mr. Redwood had been good enough to refer to him, and to say that he had given him (Mr. Redwood) some information, so that for him to make general remarks upon the geological part of the paper would be mere repetition. He could quite agree with what Mr. Redwood had said as to the general coincidence between the occurrences of petroleum and the course of mountain ranges in Europe. A geological map would show that the mountain ranges coincided with the geological structure. Perhaps he had not fully understood Mr. Redwood in some of his remarks with reference to the supposed connections of distant localities. He would hardly, for instance, be inclined to connect the petroleum of Algeria with that of the South of Spain. He was rather inclined to think that in Algeria, when the course of petroleum was more fully known, it would be found to lie in an east and west direction, extending for some distance along the hills. He did not see any geological reason for connecting the petroleum of Hanover with that of the Carpathians. He would rather connect the Carpathian ranges with that very interesting case in Bavaria, south of Munich; this was plainly suggested by a geological map. As regards the varying chemical compositions found in different geological formations, it was very easy to compare the composition of petroleum of different formations from different places, but what they wanted was a minute comparison from different formations in the same district, and he thought that could be done in Galicia. As regards the varying density of different petroleum deposits, very often it appeared that petroleum at greater depths had a lesser specific gravity. As Mr. Redwood had pointed out, one would expect this, because the petroleum near the surface would lose some of its volatile matter, but an inspection of the tables exhibited scarcely seemed fully to bear that out.

Mr. NELSON BOYD said that Mr. Redwood had shown them the methods which were originally used with hand labour, and then proceeded to show them the drilling apparatus which was used now, namely, the Canadian, but which he (Mr. Boyd) would prefer to call the American system. The best method for classifying the systems of drilling was based upon the tools that were used in the borehole itself. In the American system, whether worked by rods or rope, the tools used were the same. In Canada they used 2-in. rods, whereas in Pennsylvania they used the rope system, which was very useful for deep wells. The systems were really exactly the same. With reference to the Canadian system not being suitable for deep boring, he had had a hole drilled no less than 613 metres deep, and he thought that that was a feat which had not often been

accomplished with rods. When wells were sunk to 1,400 or 1,500 ft., a rope was usually adopted, and there the rope system had the advantage, as it was more expeditious. In fact, where one got beyond 300 or 400 yards, it took very nearly half an hour to draw up the rods. The free-fall system had been universally used in Europe for boring for water, and it had also been adapted for other borings. This system had been described as very good, but then it involved the necessity of iron rods. The result was an enormous weight and a very slow bringing up of rods, with consequent increase in the expenditure. He thought that the American system was infinitely superior to it. The system used on the Continent was a modification of the one before them, but instead of hand labour they used an engine. There was also the so-called diamond drill, which ought to be called the crown drill, because it was not absolutely necessary to have diamonds at the bottom of the crown. He had himself seen an apparatus for boring with a preparation of emery which was sufficiently strong to go through soft ground. In beds of clay in which petroleum is found, the diamond drill was absolutely useless; it clogged in the clay, the crown had to be given up and the chisel used; and then a pulp of fine sand and clay was formed, which remained in the hole; and not only that, but the rotary action of the chisel formed cavities all round. He supported Mr. Redwood in the opinion that the Canadian system was infinitely the best of the three. It should be remembered that the Northern Carpathians were very much steeper on the northern side than on the southern side, and therefore people working on the southern side would strike the oil line at a less depth.

Mr. GEORGE MORDAUNT might say, with regard to this petroleum, that it was well known in England, and as far back as the years 1865 and 1866 about 1,000 tons had been imported to London, and was refined by the Hydrocarbon Oil Company at Southall. At that time the price of refined petroleum was 2s. 9d. per gallon, whilst at the present moment it was $4\frac{1}{2}$ d. Between 1864 and 1892 enormous quantities of American, Canadian, and Russian oils had been imported. The import into London in 1864 was 45,211 barrels; last year it was 1,244,115 barrels. That would give some idea of the marvellous development of this trade. The members of the oil trade were extremely pleased to see these new developments leading to increased production all over the world, because they felt convinced that, by the aid of chemists and engineers, petroleum would sooner or later be adopted for fuel, and also as a motor for steamships.

Mr. W. J. A. BUTTERFIELD wished to ask Mr. Redwood two or three questions on the applications of petroleum. Mr. Redwood had mentioned the extensive use now made of oil for making gas, and for carburetting water-gas. Oil for this purpose should be free from water, and he was not very clear whether the petroleum from Galicia was free from water. He did not understand also whether the petroleum was free from sulphur, or whether this was only the case with the ozokerite. He would also like to know whether, on distillation, the oil gave off any ammonia or not. He thought it would be interesting to ascertain if the oil-fields of America were co-extensive with mountain ranges, as were the oil-fields of Europe.

Mr. W. PAYNTER said he had been investigating the existence of oil in North Africa during the last two years, and was of opinion that that oil-field would prove an important one in the near future. In the borings he had made on the southern slopes of a range of the Atlas mountains, and from other surface indications, the oil showed very plainly over a distance of 20 miles. The oil-fields in the district of Ann Zelt, in the Atlas mountains, corresponded exactly to the description of those in the Galician mountains which Mr. Redwood had given them. His personal experience completely bore out what Mr. Redwood had said, and he would venture to say that if they studied the origin of petroleum it would be found to exist in Europe and Africa principally near limestone of the tertiary period. The specific gravity of the Galician oils from 900 down to 764 were exactly what he had found at various depths. At a depth of 14 or 15 yards he found it

to be 860. He had found that Am Zeff oil contained from 6 to 7 per cent. of solid hydrocarbons. Mr. Redwood had found 5 per cent., but he had since come across some samples of oil which contained nearly 8 per cent. It seemed to him that in North Africa they had another extensive petroleum field, and the company in which he was interested was the pioneer company in developing this field. "Am Zeff" is Arabic for "pitch wells."

MR. REDWOOD, in reply, said that with reference to Mr. Topley's remarks, he did not desire to carry the argument of the north-west, south-east line too far. He did not wish to pose as an exponent of the view that on the continent of Europe these deposits must occur on such a line. He had thought it expedient to point out that the petroleum fields to which he had occasion to refer occupied the relative positions described. He did not desire to advance any opinion on a geological question in opposition to the views of Mr. Topley, and he quite agreed with him that new deposits might be discovered, which would necessarily modify the generalisation attempted. But, nevertheless, there was in his mind an idea that some sort of general disposition on parallel lines running, broadly, north-west, south-east, characterised the petroleum fields of Europe. He was fully in accord with Mr. Topley in thinking that a chemical comparison of petroleum from the various geological horizons in Galicia might prove to be exceedingly interesting and valuable. He might say, however, that he had worked out that idea a little farther in his paper, than he had, from lack of time, been able to indicate that evening; but while he felt that a careful study of the relative physical and chemical characteristics of various samples of petroleum obtained from the different geological horizons in Galicia might lead to important results, it did not appear to him that any very definite deductions could be drawn from the existing data. He would like to make one remark in reference to Mr. Topley's comments on the results obtained in the examination of samples from a number of wells in the Sloboda district. In consequence of the fact that in Galicia it was not an uncommon thing to perforate the casing, not only at the lowest oil horizon, but at every important oil horizon, a product was frequently obtained in variable proportions from different horizons. With respect to Mr. Boyd's observations he might remark that he had found it convenient to apply the terms American and Canadian respectively, to the systems of drilling with a cable and with rods. He quite agreed with Mr. Boyd that the tools were of the same description, but he believed that the names in question were appropriate, since the rope system was generally used in the United States, and the rod system in Canada. He did not think that the remarks made by other speakers called for any reply, except those which had fallen from Mr. Butterfield, who asked some questions in reference to the employment of Galician petroleum as a source of gas for carburetting purposes. Mr. Butterfield had pointed out in the first place that the oil for this purpose should be free from water; and he had inquired if Galician petroleum was free from sulphur. As a matter of fact, crude petroleum which had a specific gravity considerably different from that of water could not long retain much water in suspension, and the quantity which would remain in solution might be disregarded in the use of the oil for gas-making purposes. The crude oils which had given trouble in gas making, owing to the presence of water, had been of a high specific gravity. From such oils water separated but very slowly, by subsidence at common temperatures. As regarded freedom from sulphur he might say that the petroleum found in Galicia was usually practically free from sulphur. He might add that the presence of sulphur in petroleum employed in gas making was a matter of much less consequence than its presence in crude oil intended as a source of kerosene, for it was comparatively easy to remove sulphur from gas.

Meeting held Monday, February 1st, 1892.

MR. THOS. TYLER IN THE CHAIR.

THE STABILITY OF CERTAIN ORGANIC NITROGEN COMPOUNDS OCCURRING IN COAL-TAR PITCH.

BY WATSON SMITH.

(*Lecturer in Chemical Technology in University College, London.*)

THIS note is merely designed to call attention to a fact that appears to have been overlooked, as well as to point to a very simple lecture experiment for the purpose of illustrating that such organic substances as pitch, which contain small quantities of nitrogen in combination, if ignited so as to become reduced to a porous coke, evolve a considerable proportion of that nitrogen as ammonia. The exhalation of ammonia from the porous coke is most marked when the ignited residue has cooled down to such an extent that the retort or other vessel is so warm that it can just be borne upon the hand for a short time. No odour of ammonia is perceived whilst the retort or other vessel is still very hot. This evolution of ammonia is secured even long after attaining a period in the distillation, when absolutely no more solid or liquid distillation products come off in the case of pitch, clearly proving that the nitrogen carbon compounds of the pitch are those which are the most stable. The fact also that the nitrogen is finally evolved as ammonia would appear to prove that some hydrogen is present and is retained in a stable form. To endeavour to show that it is not due to the influence of the moisture in air aspirated back into the retort after cooling of the latter, a set of drying-tubes were adjusted to the retort, so that the air passing back should be dry air. Ammonia was still evolved. Nevertheless, it is quite conceivable that before the adjustment of such drying apparatus, and after the removal of the lamp flame, back suction of moist air may have occurred, before the drying tubes could be fixed, as also whilst the source of heat was still present, and during lapses of the intensity of the flame.

An interesting and effective lecture experiment to illustrate this stability of nitrogen, is very simply performed, by introducing some bits of pitch into a small retort, placing a flame under the bulb of the retort and heating strongly until all that will distil over has passed off, and the residue has become red hot, and the glass of the bulb is somewhat warped and has become semi-molten. The lamp is then removed, and the retort let cool until the heat of the bulb can be just endured in the palm of the hand. On removing the stopper of the retort, the stem being still inclined downwards, a current of air passes up the stem, through the retort and through the stopper-hole, after the manner of the draught of a chimney. If the nose be now held in the ascending current of air from the stopper, a powerful, in fact, unendurably strong odour of ammonia is perceived, producing dense white fumes with the moistened stopper of a hydrochloric acid bottle. Meanwhile, as an instructive, simple, and I believe new lecture experiment I thought it not unworthy of record or of presentation to this Society.

DISCUSSION.

MR. WILLIAM CROWDER said that he did not quite see what the peculiar reaction was in the case of the pitch mentioned by Mr. Watson Smith. It was a very well known thing that in distilling nitrogenous substances a residue of charcoal was found, and that that charcoal always contained nitrogen. He himself had distilled large quantities of animal matter, and he had invariably obtained nitrogen in the charcoal. He had found exactly the same thing in the case of bone; and, in fact, it was well known that if any organic substance were distilled there was always a residue of nitrogen left in the substance. He therefore did not see what Mr. Watson Smith was driving at in singling out pitch as a substance having anything peculiar about it.

Dr. C. R. ALDER WRIGHT had noticed that sometimes nitrogen was evolved in another form, cyanogen, when the residue in the retort was coked; sometimes ammonia and cyanogen were obtained together. On redistillation of bone oil (Dippel's oil), a large quantity of ammonia was formed when the residue left in the retort approached carbonisation, and one would also frequently find a white sublimate in the neck of the retort. This consisted partly of ammonium cyanide, the cyanogen being easily recognised by dissolving in water and applying the Prussian blue test; the smell of ammonia was persistent all through the latter part of the distillation. Bodies analogous to those in bone oil would be probably contained in small quantity in ordinary coaltars, and the formation of ammonia would probably be noticeable there also to a lesser extent.

The CHAIRMAN asked what percentage of ammonia had been found in such coke material, and whether it was not possible that the nitrogen of the air might be concerned in the formation of the ammonia?

Mr. WATSON SMITH said, in reply, that the exhalation of ammonia from the coking and coked pitch did not appear to commence until after cooling had set in, and in fact to a temperature that could just be borne by the hand. Whilst other substances containing nitrogen, such as bone-black, &c., might similarly exhale ammonia, he had never observed the phenomenon so strongly marked as in the case of pitch, and he had first observed it in 1869 when continually experimenting with pitch on a large scale in a tar distillery. On reheating the coked residue after it had ceased to evolve a smell of ammonia and then letting the residue again cool down, a fresh exhalation commenced. Some further experiments would be required to prove whether or not the nitrogen of the air was at all involved in the development. It seemed scarcely probable. He had indeed tried the experiment with coked sugar, but without evidence of a trace of ammonia. The probability suggested by one speaker that the compounds decomposed might be cyanides and sulphocyanides seemed likely, especially since the ammonia was accompanied occasionally by a smell of sulphuretted hydrogen, and occasionally by a faint one of hydrocyanic acid. The best way to obtain all the nitrogen of nitrogenous cokes of any kinds, as ammonia, was to pass steam through the red-hot material until all was consumed but ash, and in suitable apparatus for the condensation and recovery of such ammonia. This was no new thing, but was well-known to and for long practised by the firm of Brunner, Mond and Co., to the best of his knowledge, in the case of coal.

The CHAIRMAN said that the point whether the nitrogen of the atmosphere had anything to do with this evolution of ammonia ought to be settled; and the fact mentioned by Mr. Watson Smith that no ammonia was perceptible whilst the contents of the retort were very hot was certainly singular. It would not be at all a difficult thing to determine by experimenting with some neutral gas. Mr. Smith admitted that the investigation was incomplete, but was put forward as a suggestion to be worked out by those whose opportunities were larger than his own.

MR. A. NORMAN TATE IN THE CHAIR.

MODERN LEGISLATION IN RESTRAINT OF THE EMISSION OF NOXIOUS GASES FROM MANUFACTURING OPERATIONS.

BY A. E. FLETCHER,

*H. M. Chief Inspector under the Alkali, &c. Works
Regulation Act.*

LAST year I read a paper on this subject before the Congress of Hygiene meeting in London. On that occasion I sketched the course which such legislation had taken, and spoke of the effects produced. This evening I have the advantage of addressing an audience well acquainted with the practical bearing of the subject, and propose therefore to take now a step in advance, and, referring briefly to what has been done in the past, to set forth, and possibly lead to a discussion on, the line of action that should be taken in future.

By way of preface I would remind the Society that the Alkali Works Regulation Act of 1863, was, as far as I have been able to discover, a new departure in the legislation not only of this but of any other country. Prohibition of noxious trades there have been, and local Acts to regulate the locality of factories where noxious trades were carried on; but there had been before 1863 no Act of the Legislature whereby an admission was implied that the emission of noxious gases was in certain cases unavoidable, and that such would be subject to definite regulations. The Act of 1863 recognised the existence of alkali works, and the fact that acid gases liable to injure surrounding vegetation were discharged from them. There was no attempt to put a stop to such works on account of the admitted injury they were liable to inflict on the neighbourhood, but steps were taken to limit that injury, and to oblige the manufacturers to adopt means for reducing the evil to the smallest possible amount.

I think I am right, therefore, in saying that in this Act a new principle was thus introduced, one differing widely from that of simple repression, hitherto applied whenever an admitted evil of the kind was dealt with. There was herein an acknowledgment that with the evil there was associated a greater good, and that to sweep away the one would be

to destroy the other; that it must suffice to restrain the evil, to insist on the adoption of the best practicable means for diminishing it to the furthest possible limit.

A second important principle in the Alkali Act of 1863 was that its administration should not be placed in the hands of the local authorities. The larger manufacturers, proprietors of chemical works, and others interested in the carrying on of processes which might cause the occasional discharge of noxious gases, are obviously not those who should be entrusted with the administration of a law to control those operations in which they are particularly concerned. It was felt to be necessary therefore that the inspectors to be appointed under the Alkali Act should be removed from all local influence, and that they should be appointed by the central authority.

For this and for other reasons it was probably thought that the local medical officers of public health would not be suitable agents for carrying out the new law. Their medical studies eminently fit them for their office as guardians of the public health, but they are not necessarily students of chemistry nor familiar with its application to the arts.

The appointment of inspectors who should have power of entry of the works registered under the Act was also new and seemed to be in opposition to our instinctive feeling of the inviolability of private property. This step was, however, necessary to the carrying out of this newer legislation.

If it were conceded that a work should not be stopped though it might have been ascertained that some noxious gas escaped from it, provided that such escape were kept within the narrowest possible limits, then there must be inspectors to ascertain the fact, and they must have opportunity of continually examining the process and the apparatus.

As the number of chemical works increased and they were grouped together in considerable numbers, as at Widnes and St. Helens, it was found impossible for a farmer in the surrounding district whose crops may have been injured by an acid gas to fix on the factory whence this had proceeded. The work of an inspector became therefore the more necessary to go before and prevent the injury, or, if necessary, single out the offender. It being then conceded that if certain chemical manufactures were carried on some noxious gas would inevitably from time to time escape, and inspectors being appointed to examine with a view to minimise the amount thus escaping, it became necessary to give a standard for their guidance, to fix a limit beyond which any emission of a noxious gas should be considered penal.

In the original Alkali Act of 1863 the only gas dealt with was hydrochloric acid. That gas, liberated by the action of sulphuric acid on common salt during the first stage of its conversion into alkali by the Leblanc process, was in the early days of the manufacture allowed to pass into the fire flues, thus finding a discharge through the chimney into the atmosphere. The first effort to mitigate the damage thus inflicted on surrounding vegetation was to heighten the chimney in the hope that, carried to a distance, the acid gas by extreme dilution would be powerless for evil. Thus rose the tall structures once seen at Newton, in Lancashire, and that still standing at St. Rollox, in Lancashire. It was when the failure of this palliative was realised that Mr. Gossage constructed his now famous towers for the condensation of hydrochloric acid gas. Brought here into contact with water distributed over large surfaces it was dissolved and retained as a liquid acid.

It was the operation of these condensing towers that gave a standard for the Alkali Act. Their action was so nearly perfect that it seemed safe to engage that 95 per cent. should be condensed. Thus it was made penal for an alkali manufacturer to allow more than 5 per cent. of his hydrochloric acid to escape into the air. As the number five has no particular relation to common salt or hydrochloric acid, or to the molecular weights of either, it must be admitted that it was taken as a conveniently familiar figure, and sufficiently near for a first attempt. As a fact the manufacturers from the first kept well within it, indeed the amount of acid escaping from the condensers themselves was very much below the proportion named. At the present time, adding to this the amount which escapes

through crevices in the furnaces, or in other ways finds its way into the chimneys, the whole does not exceed on the average 2 per cent.

The Alkali Act of 1863, containing the novel principles here indicated, was passed tentatively for five years only. During this first time of trial it worked satisfactorily, the amount of acid gas found to be escaping from some of the works was rapidly diminished, the presence of an inspector was not found to be excessively offensive, and it was said that in some districts a marked improvement could be observed in the neighbourhood of chemical works. In 1868 the Act was therefore renewed and made perpetual.

The standard of a condensation of not less than 95 per cent. was still the only one upheld by the Act. It is said that this had been readily agreed to by those who represented the manufacturers in the committee of the House of Commons, as it was believed that no means existed for determining the total amount of acid escaping from any work, so as to calculate the proportion it bore with the quantity generated. In order to estimate this it was not sufficient to compare the relative acidity of the air or gas entering the condenser with that leaving it, for should there be leakages in the furnaces some gas might find its way to the chimney without passing through the condenser. It was seen that the total amount passing up the chimney during any given time must be estimated, and a proportion determined between that and the total quantity being generated during the same interval. No means were, however, available for giving all the factors necessary for this calculation. A measured volume of the gases passing up a chimney or through a culvert might be withdrawn, and the amount of hydrochloric acid there contained determined, but there was no means of estimating the quantity of those gases which passed in a given time. In order to do this an anemometer was needed, by which one could measure the speed of air of any temperature, even if red hot, and when charged with corrosive acids, or if heavily laden with dust or soot. But no such instrument was provided or was known. It was only after much investigation and the independent work of one of the inspectors that this problem was solved, and an anemometer constructed which should measure the speed of a current of air even under the adverse conditions named.

Apparatus was also needed for ascertaining the amount of acid gas in a given volume of mixed air. Some means of withdrawing a measured portion of air from the chimney or smoke culvert were in the hands of chemists, and for ascertaining the quantity of acid gas contained in it, but it was the good fortune of one of the inspectors under the Act to devise an apparatus portable and specially convenient for the purpose in hand. It took the form of a collapsible cylinder constructed of ebonite and vulcanised rubber, in size capable of holding one-tenth of a cubic foot. The solvent for the acid or other body contained in the air aspirated was introduced into the collapsible aspirator, where on agitation it was brought well into contact with the contained gases.

Thus armed with anemometer and collapsing aspirator and a few bottles of standard solutions, it was in the power of an inspector rapidly to determine from his own observation what proportion of the hydrochloric acid produced in an alkali work was allowed to pass through the smoke flues and chimney into the air.

The result of this was a notable diminution of the amount of hydrochloric acid allowed to escape from the alkali works, a result achieved not by means of numerous prosecutions, but by pointing out whence and how the escape took place. The chief source of this was a faulty method of setting the decomposing pots, also leakages in the inner arch and bed of the muffle furnaces in which the saltcake was roasted. Before long all the Lancashire saltcake furnaces were modified, so as to obviate the faults thus pointed out; the decomposing pots were set so that the rim was not buried in the brickwork as formerly, but exposed to view, thus rendering it impossible for any gas to pass round it into the furnace flues beneath. As to the roasting furnaces, those of the older construction, found so often to leak and allow much of the hydrochloric acid to follow the draught of the chimney to be thus discharged into the air, were

replaced by furnaces wherein a slightly higher pressure was established in the fire flues surrounding the muffle of the furnace than in the muffle itself, thus neutralising the tendency for the acid gases to pass away with the smoke. These were called *plus-pressure* furnaces. As pioneers in their construction we are indebted to Messrs. Gamble and Son, of St. Helens, and Messrs. Gaskell, Deacon, and Co., of Widnes.

It may thus be said of the inspection established under the Alkali Act, that by introducing an exact system of estimating the character and the amount of the waste gases passing into the atmosphere, and by inducing the manufacturers to daily repeat these tests and keep a constant record of the results, a gradual reformation has been effected in the construction of apparatus and the conduct of works generally.

After the renewal of the Alkali Act in 1868 a further period of six years elapsed, when an amended Act was passed in 1874.

It had been found that it was possible to carry on the condensation of the hydrochloric acid generated in alkali works till far more than 95 per cent. of it was arrested, yet the amount which still escaped from large works was in some cases so great that unless much diluted with other gases it was still highly dangerous to vegetation.

It was considered, therefore, that a further standard of condensation should be adopted, also that other gases than hydrochloric acid should be placed under control. Accordingly in 1874 an amended Alkali Act was passed, wherein it was provided that no gas or smoke containing more than two-tenths of a grain hydrochloric acid should be allowed to escape into the atmosphere.

It was enacted also that the best practicable means must be adopted for preventing the escape of all other noxious gases, besides hydrochloric acid, which are generated in an alkali work. The term noxious gases is defined to include sulphuric acid; sulphurous acid, except that arising from the combustion of coals; nitric acid, or other oxides of nitrogen; sulphuretted hydrogen; and chlorine.

The adoption of the standard of two-tenths of a grain of hydrochloric acid in a cubic foot of air was not to supersede the former standard of 5 per cent., but run with it. The two together formed a complete check upon any excessive escape of this gas. The introduction also of the injunction to use the "best practicable means" for preventing the escape into the air of certain other noxious gases was a great step in advance. When a numerical standard is adopted it is necessary that it should be loose, lest in some cases it might be found to be oppressive; indeed, the same standard may be unduly loose under some conditions, yet unfairly severe in others. The obligation, however, on a manufacturer to adopt the "best practicable means" for the avoidance of that which may be a source of injury to his neighbours, is one which he can never in justice seek to evade, or of whose fairness he can rightly complain.

The work of inspection under the now amended Alkali Act continued, yet farmers and others in the neighbourhood of the accumulated chemical works still complained that the evils from which they had suffered were not removed. In explanation of this it should be noticed that the past 15 years had been a time of rapid increase in all chemical industries. In the year 1864 the amount of salt decomposed in the alkali works of the kingdom was 288,100 tons; this increased till it has reached the large total of 855,000 tons, showing an increase of 200 per cent. This rapid increase had neutralised the controlling effect exercised by the Alkali Act. Indeed when it is remembered that the consumption of coal had reached, both in St. Helens and in Widnes, the large amount of about one million tons annually, and that the sulphurous acid from this as well as that from numerous copper-smelting, glass-making, and other works passed unrestricted into the air, it will be felt that the repression exercised by the inspection under the Alkali Act in enforcing the condensation and arrest of hydrochloric acid was quite overshadowed by this widespread pollution of the atmosphere. The inspectors could only draw consolation from the fact that if their influence were to be withdrawn a very great addition to the damage in the surrounding country would soon become apparent.

Under these circumstances a Royal Commission was appointed to inquire into the past working of the Alkali Act, and to report with a view to further legislation.

In 1881, therefore, an amended Act was passed superseding the previous Acts. In this some other branches of chemical manufacture were brought under the inspection hitherto reserved for the alkali works. It was not made generally a noxious gases Act, but under it cognizance is taken of those processes of manufacture only which are there specified, namely, sulphuric acid works, chemical manure works, gas liquor works, nitric acid works, sulphate of ammonia works, and chlorine works, also salt works and cement. Concerning these, no numerical standard is given, but it is provided that the "best practicable means shall be adopted for preventing the discharge into the atmosphere of all noxious or offensive gases evolved in such works."

The increase made in the number of works now brought under inspection was great, as is shown by the recent annual reports under the Alkali Act. In the year 1890 the number of works in the United Kingdom and Ireland registered under the Alkali Act was 1,034, while of these 133 only were alkali works, the larger majority being those coming under the classes mentioned in the schedule to it.

Such is a sketch of the history of the legislation for controlling the discharge of noxious gases from certain processes of chemical manufacture, but from certain processes only. There are, however, other processes from which noxious gases may proceed, and in most cases the gases which are omitted are the same as those which escape from the scheduled processes, yet they do not come within the scope of the Alkali Act, and the inspector cannot interfere. This anomaly presents itself, for instance, markedly in the case of nitric acid. If a manufacturer of this acid allows any to escape owing to the leaky condition of his apparatus he lays himself open to the penalties fixed in the Alkali Act, but if he sells that acid to his next door neighbour who by careless use or otherwise evaporates the whole, driving it into the atmosphere, he is not amenable to the law under the provisions of the Alkali Act. Again, if this manufacturer, who in the ordinary use of the acid in oxidising metals, was accustomed to discharge into the air the whole of the nitrous fumes thus produced, which, as stated, would be no offence under the Alkali Act; if he, by a process now commonly adopted, commenced to collect this acid and by reconvert it into nitric acid condensed it so as to prevent its escape and the consequent contamination of the atmosphere, he at once comes under the provisions of the Alkali Act, and can be brought under a penalty if any considerable quantity of it escaped.

Many anomalies of this kind may be pointed out, they arise from the difficulty or impossibility of scheduling all the manufacturing operations which should come under the control of a noxious gases Act. A list, indeed, which is complete to-day, may be no longer so to-morrow, owing to the rapid and constant advance in chemical industry. This difficulty may, however, be met by enumerating the noxious gases themselves rather than the processes of manufacture which generate them. Nor is this difficult; their number is but small. Probably as short a list as the following will be found to include all those gases with which it would be necessary to deal in such legislation as we are contemplating, namely:—

The acid compounds of sulphur, nitrogen, chlorine or fluorine. Chlorine. Fumes containing lead, arsenic, antimony or zinc.

Indeed, some may think it unnecessary even to go so far as to specify any noxious gases at all; they would style the proposed enactment, "An Act for the control of noxious gases" or "a noxious gases Act." The definition of a noxious gas might be "a gas which is complained of" or which is notoriously a cause of complaint, or which in the opinion of the inspector appointed under the Act is liable to cause complaint.

The enactment would be that every manufacturer must use the best practicable means for preventing the discharge into the atmosphere of any such gas evolved in his work.

To guard against frivolous complaints being brought against a work it might be defined that any such complaint

must be brought by, say, 10 neighbouring householders, or a complaint held to be *bonâ fide* by the Local Government Board or other central authority. Such an enactment would certainly have the merit of simplicity; it would also be comprehensive, and I do not think it would be indefinite. It is certainly clear, I think, that in future the term "Alkali Act" should no longer be used. The term "*Acid Act*" would be more appropriate. Though the title "alkali" stands over the present Act, yet simple alkali works, such as these for the manufacture of caustic soda, or those where the ammonia-soda process is carried on, do not come under it; it is only those works where acids are made which come within its scope.

Should a fear be entertained that without a more precise description of the gases to be controlled and some definite standard by which to measure the amount of acid, &c., discharged into the air, manufacturers might be harassed by restless inspectors, I would reply that the past experience of the conduct of inspectors has not been such as to warrant such fear, and remind the objector that no prosecution under the Act could be maintained until the inspector were able to convince a judge and jury that the best practicable means had not been adopted for the suppression of the evil under complaint. To do this he would probably have to point out some means that were acknowledged to be practicable and were in common use for attaining the end in view. This, too, he must do in the face of skilled witnesses that might be brought to confront him in open court. It is certain that no inspector would subject himself to such an ordeal unless he had a very strong case to maintain.

With these remarks I leave the subject in your hands, anxious to hear the view of the Society, many of whose members have had long experience of the present Act, and who habitually see its working, viewing it from another standpoint than that of the present speaker.

DISCUSSION.

Mr. TATE remarked that looking at the effect of legislation during the time that the Alkali Act had been in force, he thought it must be admitted that it had in many ways conferred advantages upon manufacturers themselves, especially owing to the way in which the Act had been worked under the auspices of the first inspector, Dr. Angus Smith, to whom manufacturers owed a great debt of gratitude for taking action in the way he did. It showed the difference between inspection by men well acquainted with the operations they had to inspect, and unintelligent inspection carried on in the ordinary policeman-like manner. Dr. Angus Smith had set himself to work to make the Act not only serviceable to those who were injured by the emanation of noxious gases, but had thought also of the difficulties under which manufacturers laboured, and so manufacturers were not unduly harassed by him. He made himself thoroughly acquainted with what manufacturers could and could not do, and endeavoured to enforce what was feasible. As Dr. Smith worked, so had other inspectors. They had one and all done their best, rather to carry out the provisions of the Act by assisting manufacturers to do what was necessary, than harass them with legal proceedings. Consequently benefit had been conferred all round. The inspectors had thrown themselves thoroughly and intelligently into the work, as for instance, in inventing pieces of really serviceable apparatus for the measurement of escaping gases, and in that respect he believed no person had worked more energetically than Mr. Fletcher himself. His apparatus has been largely used, and so had other apparatus designed by other inspectors.

Altogether, he (Mr. Tate) considered the operation of the Act as decidedly beneficial, and this because it had been worked under such an excellent system of inspection.

Mr. CAREY said he had listened with great pleasure to Mr. Fletcher's very interesting paper and to the review he had given of the progress of legislation from its first inception in 1863 to 1881, and as he (Mr. Carey) was familiar with the subject during the whole of that time, Mr. Fletcher's account had been extremely interesting to

him personally. He could support the lecturer's remarks in almost every respect, especially in regard to the spirit in which the Acts had been worked by the inspectors. If it had not been for the judicious way in which Dr. Smith, Mr. Fletcher, and other inspectors had acted, they would not have seen anything like the improvement in dealing with noxious gases which had taken place. It was desirable that the inspection of noxious vapours should be in the hands of the central authority, and that the inspectors should be men of high education and character; it was owing to attention to these two points that the Acts had been so successfully carried out. The only point on which he had always felt inclined to say, "Well, don't go too far," was about the great benefit that was alleged to have accrued to manufacturers owing to these Acts. It was quite clear that the condensation of HCl. had been of benefit to the manufacturer up to a certain point. But if it was a benefit to condense, up to 95 per cent. for example, it did not follow that there would be a proportionate benefit by condensing 97 or 98 per cent. These last one or two degrees cost more money than they were worth from a manufacturing point of view.

He agreed with Mr. Fletcher that it was unsatisfactory to schedule the works, and that it would be better to schedule the gases. But the objection that he had heard taken to that course was that if the gases were scheduled the inspectors would be obliged to visit works in a disagreeable or inquisitorial manner. He understood that Mr. Fletcher's reply to that criticism was that he did not propose to inspect these works until some complaint had been laid by a number of responsible persons. But he (Mr. Carey) was not sure that that reply was quite complete.

Under the present system of scheduling the works there are great anomalies. In some works it is not practicable to condense sulphuric acid arising from the decomposition of sulphate of soda. These works are therefore not scheduled or inspected, but if the gases were scheduled all the works making these gases would at all events be inspected, and if the inspectors continue to act in the same spirit as they had acted in the past he did not think that those manufacturers would find that they had any cause to complain. He would be glad to see the alteration made.

Professor CAMPBELL BROWN hoped the alkali manufacturers would, like the fabled fox who had lost his tail, endeavour to persuade other manufacturers whose processes emitted noxious gases or fumes, to submit to inspection under a general Act applicable to all.

He was quite sure it would be only fair, and of great benefit to the public. The inspector was no longer dreaded, but often welcome. Mr. Fletcher had indicated a preference for an Act to schedule gases rather than works, but he could not help thinking that it was a mistake to persist too long in piecemeal legislation. Of course it was right to begin tentatively, but it was now time for Parliament to pass a general Act providing that any works which emitted noxious gases should be subject to inspection in the same way that certain works now are. Of course it would not do to define noxious gases as "something that anybody complained of." They knew that if one were to manufacture pure oxygen and turn it out into the air in great quantities to benefit one's neighbours, somebody or other would complain of it; but another definition might be adopted that a noxious gas was "a gas which did appreciable harm to health or property." That would be very simple and workable, because if it came to the knowledge of an inspector that anything injurious to health or property was emitted it would be his duty to investigate it. If any people complained it should be their duty to satisfy the inspector that there was injury. An Act of that kind would be far better now than an enlarged schedule of gases or of works brought under inspection. He hoped for an Act which would take cognisance of anything that did harm.

Dr. HURTER pointed out that if alkali manufacturers had not derived much benefit from inspections, they in the laboratories had. He, personally, was obliged to Mr. Fletcher for having introduced necessary apparatus and tools which proved satisfactory in a number of

analytical operations, and he would say that he had always looked forward with pleasure to the days on which Mr. Fletcher should happen to come to their works as inspector, and that pleasure was increased when Mr. Fletcher was accompanied by Dr. Smith. In that district there had never been any friction between inspectors and employees or manufacturers themselves, and so far the Acts had worked satisfactorily. In regard to future legislation Mr. Fletcher proposed to schedule the vapours instead of the works. Looking over the list of gases so scheduled, he (Dr. Hunter) was afraid that an enforcement of such limits as were now enforced in the alkali works would be a severe task to fulfil for certain other industries. To condense, for instance, the fumes to the extent to which they had to condense them in alkali works might in glass works be a different matter, and in copper works also. Mr. Fletcher would have to frame his Act with different numerical limits for different industries. To leave the definition of a noxious vapour to householders would be a very serious matter. Householders might very easily combine together to annoy a poor small manufacturer for instance.

Mr. DAGGER observed that there was one thing which the Act would not touch, a matter of serious moment, that was the smoke emitted in connexion with the potteries. It had been his lot to live for the past two or three years in the neighbourhood of pottery towns, and he did not know whether on foggy days there was much to choose between the atmosphere of Hanley or Longton and that of Widnes.

Mr. FLETCHER in reply remarked that inspectors might well wait until complaints had been made; these came usually soon enough. Where, however, it was notorious that an offensive gas or substance emanated from a works, it might be assumed that the matter should come under examination.

Discharge of dust from works had been spoken of, and a recent case had occurred where it was alleged that plants had been injured by the dust of carbonate of soda and heavy damages had been awarded. Mr. Fletcher agreed that the term noxious gases might be made to cover solid emanations of that kind. Cement works were already under the Act; they emitted a certain amount of alkaline earths in a state of extremely fine division. Many manufacturers recognised the advantage of being under the Act, finding that they are thereby assisted in their efforts to keep their works up to a high state of efficiency. They prefer the visit of the Government inspector to the interference of local officers under the Public Health Act. He had been told by a manufacturer that he would be willing to pay 100*l.* annually rather than that the office of Government inspectors under the Alkali Act should be abolished. The question of potteries had been mentioned; they of course would come under the control of a general noxious gases Act, as would also the glass and copper works, though no action could be taken in these cases until it was known how to deal with the gases which they threw out.

As to coal smoke, whenever inspection concerning this were undertaken it would be for some time a gigantic work, but the difficulty would diminish. An association had been started in Manchester with the object of accurately testing all smoke-preventing appliances; manufacturers would be wise in giving them liberal support, for they were doing for all what it was difficult and expensive for each to do separately for himself.

Meeting held February 3rd, 1892.

MR. A. NORMAN TATE IN THE CHAIR.

THE MANUFACTURE AND INDUSTRIAL VALUE OF ALUMINIUM.

BY J. H. J. DAGGER, F.I.C., F.C.S.

IN the paper I had the honour of reading before this Society in May last year I described the now well-known electrolytic method for the production of aluminium, the two processes which I noticed being that of Herault, as carried on at the works of the Aluminium Industry Co., Limited, Menhausen, and those of the Société Electro-Metallurgique, at Froges, near Grenoble, and the Hall process of the Pittsburgh Reduction Co., U.S.A. These methods are typical of the most recent advance in the metallurgy of aluminium, and it may be taken for granted that no departure will be made from the main outline of these processes in the present state of our knowledge of the conditions of the reduction of aluminium from its combinations for some time to come. In these processes and in the electrolytic process carried on at the works of the Cowles Co., in Lockport, U.S.A., the conditions are essentially the same, the electrolysis of alumina dissolved in a bath of fused haloids, salts of aluminium, and metals of the alkalis and alkaline earths, preferably the fluoride. In the process described by M. Minet in the *Compt. Rend.*, February 17th, June 9th 1889, and October 27th, 1890, the bath is composed of a mixture of chloride of sodium and the double fluoride of aluminium and sodium as expressed by the formula—

such a mixture melting at 675°. The composition of the bath is maintained constant during the operation by means of the following mixture:—

	Per Cent.
Hydrate of alumina (partly dried)	6 (Al ₂ O ₃ 2 H ₂ O) 416.4 = 48.2
Double fluoride of aluminium and sodium	Al ₂ F ₆ 6 NaF 210.4 = 24.3
Oxyfluoride of aluminium....	Al ₂ F ₆ 3 Al ₂ O ₃ 238.4 = 27.5
	<hr/> 100.0

This mode of alimentation enables the two-thirds of the fluorine given off at the positive pole to be replaced. The bath is kept at the same level by the introduction of a mixture of chloride of sodium and double fluoride of aluminium and sodium in the proportion before given.*

M. Minet claims that by his method he attains the production of 32 grms. of aluminium for one h.p. hour with E.M.F. of 4 volts, and the return of electric energy as 70 per cent. Unfortunately, however, I have been unable to obtain further information as to this process or to verify the results obtained. M. Minet's papers are, however, well worth reading, as he goes into the theory of the decomposition of fixed aluminium fluoride and tabulates the results he obtained under varying conditions of current and temperature. From my own experience and knowledge, however, the use of more easily decomposing mixtures than those of the fluorides, even the addition of chloride of calcium, as is sometimes advocated, is attended with practical difficulties and requiring much greater skill and intelligence than one could well expect from the workmen, and therefore at present the simpler methods of the three great companies will continue to supply the

* You will note that in this process it is the fluoride that is electrolysed, in the processes before described it is the alumina that undergoes decomposition, the loss in the bath itself being only very slight, provided care is taken not to let the pots get out of ore (alumina), this being shown by the increased resistance indicated by the voltmeter. Should, however, this be neglected, the current begins to act on the materials of the bath, the halogen of the salts used being given off instead of the CO produced under normal conditions.

greatest part of aluminium required, and any further development will lie rather in the cheapening of the methods of preparing alumina, and improvements in the construction of dynamos, and the application of steam, above all water power. For the metal itself there is unquestionably a very great future, and of that the specimens on the table before you tell you more eloquently and more clearly than I can hope to do. Let me again call your attention to the comparison of aluminium with our most familiar metals, and ask each one to note clearly the figures given, which show the result of tests of the average metals and do not include exceptional or highest figures that are only occasionally obtained in the testing room.

INFLUENCE OF TEMPERATURE ON TENSILE STRENGTH OF ALUMINIUM (LE CHATELIER.)

Temperature.	15°	100°	150°	200°	250°
Tensile strength in tons per sq. in...	11.68	9.5	8.1	6.3	4.8

Temperature.	300°	350°	400	460°
Tensile strength in tons per sq. in...	3.6	2.4	1.5	1.0

Here are the results of a number of tests made at Lockport on bars cast in green sand:—

Diameter.	Tensile Strength.		Elongation.
	Lb. per Sq. In.	Tons per Sq. In.	
0.327	17,444	7.78	14
0.324	18,483	8.25	23
0.320	19,577	8.73	20
0.311	20,030	8.95	20
0.318	20,144	8.99	19
0.320	19,577	8.73	18

From these figures you see that the metal in castings is about equal in strength to cast iron. When, however, the metal is rolled or drawn we get a tensile strength of 25,000 to 35,000 lb. per square inch (11—15 tons), approximating to gun bronze. The following figures are given by the Neuhausen Company showing detailed test of a metal before and after annealing:—

TENSILE STRENGTH OF ROLLED ALUMINIUM (NEUHAUSEN).

Reduction of Cross Section by Cold Rolling and Forging.	Unannealed.		Annealed.	
	Tons per Sq. Inch.	Elongation per Cent. per d.m.	Tons per Sq. Inch.	Elongation per Cent. per d.m.
20:1	Lb. 14.7 (32,928)	4.3	Lb. 6.25 (14,000)	20
80:1	16.87 (37,788)	4.2	5.06 (11,334)	19

These figures show fairly the mechanical value of aluminium, and I must again repeat what I have stated over and over again in my former papers that aluminium can never possibly take the place of steel and iron for structural purposes, such as bridges and heavy machinery; it is not a rigid metal, and its elasticity is low, though it is only one-third the weight of iron it has less than one-half the tensile strength of the best wrought iron, and one-third that of mild steel. But it is the lightest of all industrial metals, and this lightness is combined with a tensile strength not far below gun-metal when it is rolled or

drawn, and equal to cast iron in castings. It is an excellent conductor of electricity, its melting point, 700° C., is between that of zinc, 433° C., and copper, 1082, its high specific heat making it most valuable of all metals for fine castings and light machine work, and with this corrosion resistance only inferior to the noble metals. Aluminium, surely, with these properties, needs no special pleading.

Aluminium Corrosion Experiments.

In air at all ordinary temperatures polished aluminium undergoes less superficial change than any metal excepting gold and platinum, a film of oxide is formed of infinite thinness which appears to prevent all further oxidation, the molten metal in the crucible retains its lustre until the temperature passes a red heat, and only at whiteness does much loss from oxidation occur, the affinity for oxygen increasing rapidly after bright redness is passed. This freedom from marked oxidation in its molten state compares very favourably with the loss undergone during the casting and alloying of the readily oxidisable ordinary metals, there being no scale formed and so practically little finishing needed in case of aluminium castings. This you will see by some specimens of castings taken directly from the sand.

At ordinary temperature water has no action on aluminium, and as it is unaltered even by steam, would be useful for many purposes in the laboratory, and should replace entirely water bottles of copper and all fittings at present made of other and corrodible metals employed for water supply and service, combining the strength of copper with the appearance of silver and adding to these its peculiar value of lightness. Care must be taken, however, that it is not in contact with other metals, as in that case a galvanic couple might be formed and so oxidation and corrosion take place, though the extent of this is much less than the loss of copper or iron under similar conditions. For this reason, also, it is essential that the metal should be as free from foreign elements as possible, as I shall point out later on the presence of even small amounts of impurity influences the corrosion resistance of aluminium to an extraordinary extent. Water containing salt has a corrosive action on aluminium, but less than in case of iron or copper even when the metal is repeatedly wetted and allowed to dry in the air.

A plate of cast aluminium (99 per cent.)* 7 cm. long by 4 cm. wide and 0.15 cm. thick, was suspended in a saturated solution of sodium chloride and kept at a temperature of 60° C. during 48 hours. At the end of the time it was found to be spotted in places, small patches of alumina about the size of pin heads having formed on the metal. The plate being removed from the solution, washed in distilled water, gently brushed with a piece of soft rubber to detach these small flocks, was carefully dried and reweighed, showing a loss of 0.052 per cent.

A similar plate of metal† (Al 97.10 per cent., Fe 0.44 per cent., Si 2.46 per cent.) containing 3 per cent. impurity (iron and silicon) showed larger patches of alumina with small growths of flocculent hydrate covering tiny corrosive pits, the loss was 0.0078 per cent., the difference shows the manner in which the value of this and other metals may be affected by the presence of even very small quantities of other elements. An experiment carried out at Neuhausen to determine the relative value of aluminium and iron with reference to the action of sea-water gave favourable results. A sheet of this metal (24.578 grms.) of 1 d/m² exposed surface was laid in artificial sea-water (in 1,000 parts —

* Al	99.154
Fe	0.786
Si	0.060
	<u>100.000</u>

† Al	97.10
Fe	0.44
Si	2.46
	<u>100.00</u>

27 NaCl + 3.2 MgCl₂ + 2.2 MgSO₄ in contact with an iron plate during 200 hours. At the end of this period it had lost 9 mgrms. or 0.04 per cent., whilst the iron plate of the same surface lost 54 mgrms. Another sheet of same surface 1 d.m² (24.821 grms.) being in contact with air at a t° of 80°—90° in this artificial sea-water, not in contact with iron, during 18 hours only lost 3.5 mgrms. or 0.014 per cent.

Aluminium is of course readily acted upon by hydrochloric acid at all temperatures with the evolution of hydrogen. Small strips and granules of this metal will be found useful in the laboratory for reducing purposes, and has the advantage over zinc that it is not precipitated by sulphuretted hydrogen even if a large excess of this gas be used. Nitric acid has no action on this metal unless exposed above ordinary temperature or for many hours to the concentrated acid. A sheet of pure metal 1 d.m² surface (24—25 grms.) laid in cold concentrated nitric acid (36° B.) showed a loss of 0.6628 grm. on the seventh day and 1.0195 grms. in a fortnight. (Neubausen laboratory.)

The action of sulphuric acid is very slight at ordinary temperature though it dissolves the metal with evolution of SO₂ on heating.

To determine this point I exposed a plate of cast metal (99 per cent.) 7 cm. × 4 cm. × 0.15 cm. to the action of cold concentrated H₂SO₄ during a period of 131 days. At the end of this time the loss amounted to 4.970 per cent.; the surface of the metal showed a fine white matt. The action of dilute acid would, of course, be very much less, and with regard to its use in this connexion superior to copper, though not equal to lead. The presence of impurity in small quantity has a marked influence on its resistance to this acid. With a plate of 97—8 per cent., the crystalline etching much coarser, the metal was also covered with tiny pits, probably due to minute particles of silicon or ferrosilicon compounds, as a distinct trace of H₂S was evident, both by scent and action on lead paper; the loss was 4.49 per cent. And here I will just interpolate a note of a curious result I obtained on exposing a turned and polished bar of 10 per cent. aluminium bronze to the action of cold concentrated H₂SO₄. This bar was uniform in colour and lustre, but after two days' exposure I noted a dark coloured corrosion band running in a half spiral round the bar. On removing from the acid, there was a strong odour of H₂S, and lead paper was at once blackened if held close to this patch, the rest of bar being only slightly dulled and perhaps a little reddened in colour, and active corrosion seemed to be confined to this one spot. The exceedingly minute quantity of iron and silicon that had set up this reaction (probably galvanic) was indicated by the analysis and the fact that the result of the mechanical test of the bar was normal. The action of even strongest acetic acid on aluminium is slight, a plate of cast metal (99 per cent.) surface, as in my former experiments, was suspended in concentrated pure acid at ordinary temperature during 131 days, the loss was 0.24 per cent. only, and with a plate of (97—98 per cent.) metal during the same period was only 0.013 per cent. Possibly in this case the presence of silicon hindered corrosion.

An experiment with saturated solution of citric acid during 19 hours at 50°—60° C. showed a loss of 0.095 per cent. with (99 per cent. metal). The experiments tend to show the very slight action dilute organic acids would have upon aluminium, and are confirmed by some results obtained in the Neubausen laboratory, in which the metal was exposed to cold solutions of ordinary vinegar 4 per cent. (acetic acid), and citric acid (1 per cent. solution) containing salt for two days without evidence of loss, and a sheet of 1 dm² surface (weighing 24.72 grms.), after boiling for 14 hours in a solution of common salt with 4 per cent. acetic acid, lost only 47 mgrms., or about 0.29 per cent. Under the same conditions a piece of iron lost 900 mgrms. Alkalis and alkaline carbonates act readily on the metal; it dissolves easily in solution of caustic potash and soda with evolution of hydrogen forming aluminates; ammonia solution acts more slowly, but corrosion takes place after

a little time, a flocculent growth of alumina forming on the surface of the metal. Pure dry ammonia gas seems to have no action on it.

In solutions of the alkaline carbonates the metal becomes coated with a compact skin of alumina, but in this case the presence of impurities modifies this action to a considerable extent. A test plate of cast metal (99 per cent.) was suspended in a solution of 10 per cent. carbonate of sodium for 24 hours at 45°—50° C. On examining it I found it covered with a fine strongly adherent skin of alumina, which dried to a smooth enamel-like surface. On (97—98 per cent. metal) this deposit was thicker, coarser in texture, and corrosion of the metal was more clearly marked. On suspending similar plates in saturated solutions of Na₂S at same temperature the influence of even a small percentage of impurity in modifying corrosive action was still more strikingly shown. The (aluminium 99 per cent.) metal was much corroded (loss about 3.0 per cent.) and had black stains of FeS. The (97—98 per cent.) metal was corroded, deeply honeycombed, and covered with a thick black crust containing FeS, SiO₂, and alumina. The action of metallic solutions on the metal is, of course, correspondent to that of the combining acids. All chlorides, including aluminium chloride (which dissolves the metal liberating hydrogen), act readily on aluminium, the more negative metals being liberated; the presence of sodium chloride is said to facilitate the reaction. The chlorides of the alkalis and alkaline earths are, however, an exception, their action on aluminium being only slow unless in concentrated solution and at higher temperatures. Bromides and iodides have effects in proportion to their chemical activity. Nitrates and sulphates act only very slowly on aluminium. Organic salts have only very slight or no action on this metal, and in case of acid solutions may be disregarded unless in presence of common salt, which would increase the corroding power. The action of fused caustic soda or potash at a low red heat is exceedingly slight, care being taken that the aluminium is free from silicon. It is not affected by molten nitrate of potassium until redness is reached, when energetic oxidation ensues, forming aluminate. With the alkaline carbonates and sulphates the metal is oxidised, forming aluminates with evolution of CO and some separation of carbon. With silicates and borates the metalloids is liberated on aluminate being formed with the base. Molten fluorides dissolve the metal forming in case of cryolite a sub-fluoride. No flux is needed in melting aluminium, and this must be done in black crucibles or crucibles lined with alumina. Many failures to obtain good work with this metal has doubtless arisen from not bearing in mind the importance of this point, that to the founder and metal worker aluminium is a new metal and requires new methods adapted to the physical and chemical properties will differentiate it widely from the old metals. It is a metal which must be handled by skilled and intelligent workers, and will give to them the results of which we have the first promises in the specimen before you. I have gone into this question of corrosion at length because it, more than any other, will determine the limits of the use of aluminium, and the results given to you will have already suggested to your minds my possible uses for this metal. For instance, it will replace copper and brass for kitchen utensils, not only because it resists corrosion, but that in the event of any taking place the salts formed are non-poisonous. An aluminium saucepan would, while possessing the same strength, be three and a half times lighter. Vessels of aluminium would retain their heat for a longer time, an advantage in case of workmen's dinner cans for example. The slow cooling of aluminium is very marked in the case of metal in the crucible, 40—60 lb. heated to dark redness, may be left half to three-quarters of an hour without fear of its settling. Aluminium offers many advantages, and has a nicer look than tin ware, whilst stiffer, lighter, and harder. Dishes, plates, covers, and all articles now made of tinned iron might be replaced by this metal. It would also replace many vessels used in the laboratory at present made of copper or galvanized iron. Flasks and water bottles of all kinds, more especially for military service, would be advantageously made of aluminium, as they would not only be unbreakable but be lighter than the glass and

† The actual corrosion loss was 0.1375 per cent. in 94 hours at ordinary temperature.

enamelled iron at present in use. Its indifference to organic acids would suggest its use for brewers and vintners. You will notice among the specimens a cast beer tap lent by the Cowles Company.

Again, cups and flasks could, if preferred, be made of aluminium and silvered, though the metal itself has a good appearance and will not tarnish as silver does. For scientific instruments of all kinds, especially frames and tubes of surveying and astronomical apparatus, for chemical balances, and all metal work exposed to no strain above the limits of its tensile strength, aluminium, by virtue of its lightness, would be invaluable. Scales for measuring, and indicator scales of this metal would not warp or crack as do those of ivory or wood if exposed to a damp atmosphere. That aluminium can be worked with the same facility as any other metal will be evident to those who inspect the set of tubes lent by the Mannesman Tube Company. For gas and light fittings aluminium would be valuable, enabling the weight of chandeliers, candelabra, and lamps to be reduced one-third, whilst having the appearance of silver. I have not gone into the mechanical value of this metal at length, because my duty as a metallurgist is to place the metal before you with all its physical and chemical properties, and leave the application of it to the engineer and craftsman. I have not touched upon the value of this metal in alloys, because to do so would involve not one, but two or three papers; and further I have already dealt with their production and properties in my British Association paper of 1889, reprinted in your Journal, No. 9, Vol. VIII. 1889,

and in a paper dealing with their mechanical properties as a material for artillery, read before the Mechanical Section of the British Association, 1890. At some future time of greater freedom and lesser responsibility I hope to bring before your notice some additional notes on the chemistry and metallurgy of this most valuable metal. In conclusion I would express my thanks to the directors of the Cowles Company, to the Aluminium Industry Company, the Metal Reduction Company, and to the Mannesmann Tube Company, for their valuable and beautiful specimens, and also for much valuable information as to the working and properties of the metal.

The production of aluminium is given in the Chemical Trades Journal for January 23rd, quoted from the Bulletin de Musée Commercial.

	Lib. per day.
The Neuhausen Works.....	1,000
The Pittsburgh Reduction Co.....	600
The Metal Reduction Syndicate, Lim..	300
The Cowles Co.	600—700 in alloys
and the present production of the world 2,600 lb. per day.	

However, I know the figures for the Cowles Co. are altogether too low, unless they refer, as they do truly, to the English works alone, for that company's Lockport works have a constant output of 1 ton per day; this latter figure, too, would doubtless be much nearer for the Neuhausen Co.

The following figures as to the effect of temperature on the tensile strength of aluminium are given by André le Chatelier:—

SPECIMENS TO ILLUSTRATE PAPER ON ALUMINIUM, ITS MANUFACTURE AND INDUSTRIAL VALUE.

Lent by the Aluminium Industry Co., Lim., Neuhausen, Switzerland (Leisler Bock and Co., Glasgow).

- 2 ingots pure aluminium (99 per cent.).
- 5 „ aluminium bronze.
- 1 „ ferro-aluminium (10 per cent. Al).
- 1 piece aluminium tube.
- 1 „ „ sheet.
- 1 fireman's helmet.
- 1 water bottle.
- 1 folding drinking cup.
- 1 fan.
- 1 photograph frame.
- 1 ash tray.
- 2 stamped plates.
- 4 spools aluminium wire.
- 3 medals of the Queen, the Prince of Wales, and the German Emperor.

Lent by the Mannsmann Tube Co., Lim., Landore, South Wales.

- 25 double pencil cases.
- 25 single „
- 6 Couplings „
- 1 tube 4 mm. ex diameter.
- 1 „ 5 mm. „
- 1 „ 26 mm. × 24 mm. × 3080 mm.
- 1 „ „ „ 1675 mm.
- 1 „ 15 mm. × 12 mm. × 255 mm.
- 1 „ 16 mm. × 12 mm. × 255 mm.
- 2 „ 14 mm. × 10 mm. × 255 mm.
- 2 „ 13 mm. × 10 mm. × 255 mm.

Lent by The Metal Reduction Syndicate, Lim., Patricroft.

- 2 painted plaques.
- 2 „ panels.
- 1 plain panel.
- 1 „ plaque.
- 3 sand castings.
- 4 tubes.
- Pieces of aluminium wire.
- „ „ bronze wire.

Lent by The Cowles Syndicate Co., Lim., Milton, Stoke-on-Trent.

- Beer tap of aluminium (cast in sand and finished).
- Two forged bolts and nuts of aluminium bronze.
- Teaspoons of pure aluminium.
- „ „ „ after 9 months use.
- 2 books lettered with aluminium leaf.
- Small cross cast in open sand showing sharp clear casting.

DISCUSSION.

MR. TATE, in opening the discussion, asked what was the cost of aluminium.

MR. THOMPSON wished to know whether Mr. Dagger knew anything of the statement circulated in the electrical papers that works had been started in New Jersey for making aluminium on the sodium process, with cryolite-producing sodium at 7 cents per lb. Regarding the electrical conductivity of aluminium, he had always understood that it was almost equal to that of copper. He was anxious to learn whether the tubes exhibited were pressed out or drawn from the solid. Concerning cost, he had received a quotation from a firm who asked 4s. a lb. for large quantities.

MR. CAREY was glad that the Chairman and others had drawn attention to the subject of cost; he hoped to hear something on this head. One question he wished to ask, that was, if, as Mr. Dagger had stated, saline and alkaline

solutions acted upon aluminium, how far would the slightly alkaline and saline liquids met with in ordinary cooking operations injure utensils made of aluminium.

DR. KOHN asked whether the oxyfluoride of aluminium employed in the Minet process, as described by Mr. Dagger, was a natural product or only a mixture of aluminium fluoride and alumina.

MR. DAGGER, replying to the question as to the chemical method of the production of aluminium, said probably the works in New Jersey were using the double fluoride, but he had no knowledge of such a company. In his last paper, however, he described the last and most approved chemical methods of production. The Cowles Syndicate Company produced one ton per day of aluminium, ranging from 97—99 per cent. purity. The tubes, he understood, were run out from the cold metal. Touching Dr. Kohn's question concerning the use of oxyfluoride in the Minet process, he remarked that the oxyfluoride was really an artificial product, not a definite compound, but simply alumina dissolved in cryolite. The price of the metal varied, ranging from 4s. to 3s. 4d. or 3s. 2d. per lb., depending upon the purity of the metal. There had been a reduction of 1s. per lb. since he read his last paper, when he quoted 5s. The figures, 32 grms. aluminium per 1 horse-power hour, with E.M.F. of 4 volts, which he gave, were taken from Mr. Minet's paper, which he had read over carefully. Mr. Minet wrote a great deal on the results not put into operation other than on an experimental scale. The other figures, 22 E.H.P. per lb. aluminium, were the amount common to the electrical methods now in operation.

The practical difficulties arising from chloride of calcium meant in using chloride there was a greater tendency for decomposition to take place, and chloride to give off chlorine, a great nuisance in the furnace room, whereas in cases of the fluorides which had a higher fusion point, no decomposition of the bath took place so long as ordinary care was taken, but if salt be added, then decomposition of the electrolyte was more likely to take place, and very much more careful management was required. The product given off in the ordinary process was CO, not CO₂. The loss of carbon was practically 1 lb. of carbon for every pound of aluminium. The cost of current amounted to something like 75 per cent. of the cost of production. Hall gives the following theoretical cost per pound:—Alumina, 3d.; carbon electrodes, 1d.; chemicals and pots, ½d.; 22 E.H.P. water power used, 2½d.; labour and superintendence, 1½d.; general expenses and repairs, 1½d. The difficulty of soldering aluminium still remained with them, and he had heard nothing since he gave the mixtures used for soldering purposes in his last paper, though he believed that results which were said to be successful had been obtained by using fused potash as a flux. As to the sources of aluminium, for the present, production was steady and there was more than sufficient, but should there be a large demand for the metal in the future, it would tend to stimulate chemists to produce aluminium by taking rich clays, treating them with acids, and getting out alumina that way.

MR. CAREY had spoken about its use for cooking vessels; he had given him figures as to the corrosion by salt. In his experiment he had used concentrated solutions, and they would see that the loss at 60° C. during 48 hours in 98 per cent. metal was found to be 0.0078 per cent., while in the case of a pure metal it was 0.052 per cent., while the experiments of the Neuhausen Company showed only 0.29 per cent. after boiling for 14 hours, and those conditions would not be reached in ordinary cooking.

Meeting held Friday, February 5th, 1892.

MR. IVAN LEVINSTEIN IN THE CHAIR.

NOTE ON THE AMOUNTS OF TANNIC ACID ABSORBED BY COTTON UNDER VARYING CONDITIONS.

BY EDMUND KNECHT PH.D., F.I.C., AND JAMES KERSHAW, MANCHESTER TECHNICAL SCHOOL.

THE natural affinity which gallotannic acid and the other tannins possess for the cotton fibre, coupled with their property of forming insoluble compounds with metallic oxides and the basic coal-tar colours, renders these materials of great importance in the dyeing and printing of cotton.

For the application of the tannins in cotton-dyeing, two methods are principally employed, viz., by *steeping* (chiefly used for loose cotton and yarn) and by *padding* (chiefly used for piece-goods). It was namely for the elucidation of certain points in connexion with the first of these methods that we undertook the present work.

It is well known that cotton steeped in a tannin solution absorbs some of the tannin, and practical experience has shown that the amount absorbed depends upon the temperature and degree of concentration of the bath and upon other conditions of working. It is also known that the tannic acid absorbed can be completely removed by long-continued washing with cold water, more rapidly by boiling water. The only exact work which has, to our knowledge, been published on this subject is that of Juste Koechlin.*

This authority finds that cotton mordanted in a solution containing 50 grms. per litre loses all its tannin in pure water, but loses nothing in a solution containing 5 grms. per litre. It only begins to lose tannin in a solution containing 2 grms. per litre. From acetic acid and alcoholic solutions the tannin is not taken up as well as from aqueous solution.

All Koechlin's estimations appear to have been done colorimetrically, viz., by the depth of shade produced by developing the tanned cotton in a solution of acetate of iron.

That it is impossible to completely exhaust a tannin bath, is well known, but hitherto it does not appear to have sufficiently interested anyone to know how much tannin is actually absorbed by the fibre under given conditions, to make it worth while carrying out exact quantitative determinations. Since the introduction of the Lowenthal process of estimating tannin, this is rendered possible and it has been our principal aim to determine by exact methods

the actual amount of gallotannic acid absorbed by cotton under varying conditions of temperature, time, concentration of water bath, &c.

The cotton used for the experiments was a bleached two-fold 20-s. yarn. Boiled in distilled water it gave up nothing that would decolorise permanganate.

The tannin employed was a pure pharmaceutical tannic acid containing, in terms of oxalic acid—

Tannic acid	128.28
Gallie acid	3.72

The strength of the permanganate solution was 1 grm. per litre, and this was standardised with ferrous ammonium sulphate.

In each case, the tannin absorbed has been estimated not directly, but by difference, an aliquot portion of the solution being withdrawn from the bath and titrated with permanganate. By thus ascertaining the total amount left in solution, we were able to determine by difference what had been withdrawn by the fibre. The results are expressed in terms of the tannic acid used. A quantitative determination showed that gallic acid has absolutely no affinity for cotton, so that under the heading, "Left in solution," the amounts stated express the tannic acid plus the whole of the gallic acid left from the 0.25 grm. tannin employed.

In the experiments, except where otherwise stated, we used 5 grms. of cotton, 5 per cent. of tannic acid, and 30 times the weight of water (of the weight of the cotton). The cotton was entered at 100° and was allowed to cool with occasional stirring during three hours.

I. Effect of Temperature.

1. The cotton was steeped cold for three hours.
2. The cotton was entered boiling and allowed to cool during three hours.
3. The cotton was steeped at 50° for three hours.
4. The cotton was steeped boiling for one hour.

Results.

—	Tannic Acid Taken.	Absorbed by Cotton.	Left in Solution.
	Grm.	Grm.	Grm.
1.	0.25	0.0393	0.2137
2.	0.25	0.0513	0.1987
3.	0.25	0.0082	0.2418
4.	0.25	0.0025	0.2475

From this it would appear that the method adopted in practice, viz., entering hot or boiling is the best condition of temperature.

II. Concentration.

Same conditions as above, but with varying amounts of water, viz. :—

1.	75 cc. water.
2.	150 cc. "
3.	300 cc. "
4.	450 cc. "

Results.

—	Tannic Acid Taken.	Absorbed by Cotton.	Left in Solution.
	Grm.	Grm.	Grm.
1.	0.25	0.0663	0.1837
2.	0.25	0.0513	0.1987
3.	0.2	0.0288	0.2212
4.	0.25	0.0238	0.2362

* Bull. Soc. ind. de Mulhouse T. I.I. p. 438.

III. *Additions to Bath.*

Same conditions as stated at first.

Results.

—	Tannic Acid Taken.	Absorbed by Cotton.	Left in Solution.	Addition.
1.	Grm. 0.25	Grm. 0.0498	Grm. 0.2002	Per Cent. 10 Na ₂ SO ₄
2.	0.25	0.0363	0.2137	50 „
3.	0.25	0.0250	0.2250	100 „
4.	0.25	0.0363	0.2137	5 H ₂ SO ₄
5.	0.25	0.0288	0.2212	10 „
6.	0.25	0.0213	0.2287	20 „

The effect of sodium carbonate was also tried, but it was found that on adding 5 per cent. Na₂CO₃ to the tannin solution, boiling and allowing to cool during three hours (without any cotton), the amount of permanganate required increased 17 per cent. on the original amount required for the pure tannic acid. An estimation by difference was therefore impossible.

IV. *Time.*

The original conditions were again adhered to, but the time was altered.

Results.

Tannic Acid Taken.	Absorbed by Cotton.	Left in Solution.	Time.
Grm. 0.25	Grm. 0.0128	Grm. 0.2372	30 min.
0.25	0.0168	0.2332	1 hr.
0.25	0.0190	0.2010	2 hrs.
0.25	0.0572	0.1928	4 hrs.
0.25	0.0609	0.1891	6 hrs.

The tannin is still being absorbed after six hours' immersion, and although the absorption is not in a direct ratio to the time of immersion, it is probable that the limit has not been reached in six hours.

V. *Consecutive Baths.*

1. 5 grms. cotton were entered boiling and allowed to cool during 1½ hours.

2. Same as No. 1. Wring out well, then enter a second 5 grms. at 100° and allow to cool again during 1½ hours.

3. Same as No. 2, with a third lot of cotton.

Results.

Tannin used.	Absorbed by 1st 5 Grms.	Absorbed by 2nd 5 Grms.	Absorbed by 3rd 5 Grms.	Left in Solution.
Grm. 0.25	Grm. 0.0355	Grm. ..	Grm. ..	Grm. 0.2145

0.25	0.0355	0.0195	0.0103	0.1847

VI. *Washing Out.*

Enter boiling and allow to cool over night.

Absorbed by Cotton.	Left in Solution.
Grm. 0.0612	Grm. 0.1888

1. Steep in cold water (150 cc.) for one hour.
2. Steep in cold water (150 cc.) for three hours.
3. Steep in boiling water for one hour.
4. Enter into a solution of 10 per cent. tannic acid at boil and allow to cool during three hours.
5. As No. 4, using 2½ per cent. tannic acid,

Results.

—	Left in Fibre.	Tannin extracted.
	Grm.	Grm.
1.	0.0467	0.0147
2.	0.0393	0.0221
3.	None.	0.0612
4.	0.0195 + the 0.0612 absorbed	0.4802
5.	0.0007 lost.	0.1243

VII. *Bleached, Unbleached, and Mercerised Cotton.*

Same conditions as above.

Tannic Acid taken.	Absorbed.	Left in Solution.
Grm. 0.25	Grm. 0.0513	Grm. 0.1987 bleached.
0.25	0.0568	0.1932 unbleached.
0.25	0.1033	0.1467 mercerised.

The unbleached cotton was boiled previously for a short time with soap, to remove waxy and other impurities.

Precipitated Cellulose, obtained by dissolving filter-paper in Schweitzer's reagent, precipitating with hydrochloric acid, and washing thoroughly with water, is capable of absorbing under similar conditions a much larger proportion of tannin than cotton yarn. Using 5 grms. of such cellulose, 150 cc. water, entering at 100° C., and allowing to cool during three hours, we obtained the following results:—

Tannic Acid taken.	Absorbed.	Left in Solution.
Grm. 0.25	Grm. 0.1525	Grm. 0.0975

This is no doubt partly due to the fine state of division of the cellulose.

Generally speaking, our results confirm quantitatively what has been known for a long time qualitatively. It is interesting to note what a small proportion of the tannic acid employed is taken up by the cotton under the most favourable conditions. If this circumstance is taken into account, a great saving might frequently be effected, in our opinion, in the application of tannin in cotton dyeing.

NOTE ON THE ACTION OF CHLORINE ON WOOL.

EDMUND KNECHT, PH.D., F.I.C., AND E. E. MILNES,
MANCHESTER TECHNICAL SCHOOL.

THE chlorinating of wool with the object of rendering it better able to take up certain colouring matters in printing, appears to have been first suggested and carried out by Mercer. Since that time the chlorinating of all-wool and cotton warp delaines for printing has become a general practice among printers.

During the latter part of last session we had begun an investigation regarding the chemical changes which take place in this interesting operation, but owing to Mr. Milnes having accepted another appointment our work has been interrupted, and as we shall probably not be able to take it up again conjointly we wish to give in the following a short résumé of the results obtained.

Our original object was to determine whether the chlorine acted by substitution, addition, or oxidation, but unfortunately the work was prematurely interrupted. Nevertheless some points were brought to light which may be of some interest.

Action of Dry Chlorine.—Wool dried at 100° was treated for several hours in a current of dry chlorine gas. Very little change appeared to take place; a little hydrochloric acid gas was given off and the material (flannel) was not perceptibly injured. Its affinity for colouring matters is not increased.

Action of Moist Chlorine.—Wool in its natural state was treated for several hours in a current of moist chlorine. Large quantities of hydrochloric acid gas were evolved from the beginning and the edges of the flannel began to assume a gum-like, translucent appearance. Boiled afterwards in water the material lost over 60 per cent. in weight, a threadbare and tendered fabric being left behind. The aqueous solution evaporated to dryness left a brownish coloured deliquescent residue, which retains a large amount of (free?) hydrochloric acid. When heated this residue swells up and decomposes, evolving a smell of burning horn. It does not blacken alkaline lead solution, but is found to contain sulphur by the nitroprusside reaction. Its most characteristic property is that which it possesses of precipitating in aqueous solution the substantive colouring matters, as one of us found to be the case with lanuginic acid. It may be that this fact may account in some way for the increased affinity which chlorinated wool possesses for such colouring matters.

Flannel (11·13 grm.) treated for one hour with 5 per cent. bleaching powder and excess of hydrochloric acid was washed first in distilled water, then warmed for a short time with very dilute ammonia (to neutralise free acid), and then extracted repeatedly with boiling distilled water until the water showed no opalescence with silver nitrate. The wool was then dissolved in caustic soda, the solution acidulated with nitric acid, excess of sodium carbonate added, evaporated to dryness, calcined in a platinum dish, and the residue tested for chlorine. It was found to be entirely free from chlorine. This fact, coupled with the copious evolution of hydrochloric acid in presence of moisture that modification of sulphur which blackens with alkaline lead solution is not destroyed by the ordinary chlorination, and only disappears when the fibre is deeply attacked.

Another noteworthy fact is that the chlorinated wool, even after drying and exposing to the air for several hours or over night, is coloured brown when moistened with potassium iodide solution. Whether this property is due to the presence of free chlorine in the fibre or to the formation of quinone-like substances, we have not yet been able to determine. It is removed by prolonged treatment with sulphurous acid or bisulphite of soda.

In most textbooks and manuals on dyeing we find the statement that wool is deeply attacked and turned yellow by chlorine or hypochlorites. We find that dry chlorine has very little effect in discolouring wool. Neither has it this property in solution if a large excess of free hydrochloric acid be present. Free hypochlorous acid, however,

rapidly turns the wool brownish-yellow. Possibly this may account for the yellowing of pieces which sometimes takes place in working on the large scale.

Bromine acts on wool in a similar way to chlorine.

The soluble product above referred to does not appear to be formed by the action of permanganate on wool.

DISCUSSION.

THE CHAIRMAN: The results of Dr. Knecht's experiments were of the greatest importance, inasmuch as dyers have not time to make the necessary examinations, and the practical results were principally these:—They knew that immense quantities of tannic acid were used in dyeing, partly for the fixation of metallic mordant and partly for the fixation of the basic coal-tar colours, and it was evident that in this process there must be an immense waste. If dyers and printers really studied these results it would lead to considerable saving.

MR. GRIMSHAW said, speaking generally, he thought the papers were bound to be of great assistance to manufacturers in helping them to reduce what he might call the qualitative to the quantitative action, and he believed that these were the lines on which economy would be promoted in all chemical industries Dr. Knecht had mentioned. Mercier, who was a striking example of one who without adopting scientific knowledge arrived at a wonderful amount of practical results, and it was indeed strange that his name was so little known.

DR. WEBER: Dr. Knecht had told them that wool, under certain circumstances, produced lanuginic acid, which was one of the amido-acids. Would it not be probable that so strong an oxidising agent would attack this amido-acid, and thereby cause them to form a sort of condensation product of the oxidation product of lanuginic acid and the rest of the chloranil.

MR. J. CARTER BELL wished to know if Dr. Knecht had tried chlorination of the wool after it had been bleached, because it always contains a percentage of fatty matter?

DR. KNECHT replied that he had experimented with bleached flannel.

DR. KNOWLES, F.C.S., would like to suggest that Dr. Knecht should continue his researches. Delaine printing was an industry little known in this country as yet, and there was a great amount of difficulty in the proper application of colouring-matters. His mention of the application of induline to wool which was not chlorinated has a parallel in the application of naphthol black to woollen fibre. They would find that wool which is merely scoured and bleached is not capable of being printed on, whereas if chlorinated it is capable of being printed on by naphthol black, which black when properly applied is extremely fast.

LABORATORY NOTES.

BY W. F. LOWE, F.I.C., F.C.S., ASSOC.R.S.M.

(a) THE GRAVIMETRIC ESTIMATION OF ZINC AS SULPHIDE.

THE usual method of estimating zinc in blende and other ores of zinc is by a standard solution of sodic sulphide with a small quantity of ferric hydrate added to the solution as indicator, or better, with nickel chloride solution employed outside the solution as indicator; but as this method, even when most carefully carried out, does not yield results nearer than 0·5 per cent. (see Fresenius' Quantitative, vol. II., p. 281, and Mitchell's Manual of Assaying, p. 580) it cannot be considered a very satisfactory one, its only recommendation being that it is a fairly quick and sufficiently accurate for many purposes.

The great objection to it is that none of the indicators are sufficiently sharp; with ferric hydrate, for instance, the solution requires to be violently agitated during the whole of the titration and the white zinc sulphide merely turns to a dirty grey. Nickel chloride used on a white plate is somewhat sharper, but is by no means a really satisfactory indicator. The standard solution used is generally made of such a strength that 1 cc. = 0.01 grm., and for rich ore 0.5 grm. of ore is taken, a difference of 0.1 cc. is equal to 0.2 per cent. of zinc, so that a greater error than 0.5 per cent. can very easily be made.

There are also the volumetric methods of estimating zinc by means of a standard solution of potassic ferrocyanide, but these also are stated by Fresenius not to yield results nearer than 0.5 per cent.

There is also Mann's silver method, but in this the zinc is first precipitated and filtered as zinc sulphide; there is not much gained by it.

There is nothing specially novel in the method described, but it is one, I believe, that is very little used owing to the supposed difficulty of filtering zinc sulphide; but if the necessary precautions are taken very little difficulty will be found and exceedingly accurate results will be obtained. It certainly occupies more time, requiring two days, but when much greater accuracy can be obtained I do not think that a little more time and trouble should have much weight as an objection.

The sample having been first dried (samples from the mines being usually wet) is ground and the whole passed through a 60-mesh sieve, a small sample is then taken and finely ground in an agate mortar, and it is of great importance that it should be finely ground, for otherwise it will not readily dissolve in hydrochloric acid.

One grm. is taken, placed in a conical flask of about 300 cc. cap. 10 to 15 cc. of strong HCl added, the flask covered with a small funnel and boiled on an iron plate until dissolved. If the ore has been finely ground this will take place readily. Two or three drops of strong HNO₃ are then added to ensure the complete solution of the ore. This should not be added until the solution of the ore in the HCl is complete as otherwise a separation of sulphur will take place, and in such a case it is necessary to remove the sulphur, burn it and add any residue to the solution in the flask. For this reason it is not well to dissolve in a mixture of HNO₃ and HCl, as sulphur always seems to separate. In fact Fresenius recommends that the sulphur in blende should be estimated by deflagration with nitre and carbonate of soda instead of in the vat way.

As soon as all the nitrous fumes have passed off the solution is diluted to about 100 cc. with cold water, and a good stream of H₂S passed through until the precipitate turns black and settles readily. It is then filtered through a covered filter, and washed with water containing a little H₂S.

The solution is then heated in an uncovered beaker on the iron plate to a temperature just below boiling. As soon as the H₂S has passed off, some bromine water is added to peroxidise the iron, the solution cooled, and an excess of ammonia added. It is allowed to stand for a few minutes on the iron plate for the precipitate to settle, and is filtered through a large filter-paper. The precipitate is washed slightly, and is then redissolved in warm hydrochloric acid; it is reprecipitated with ammonia and filtered through the same paper, and is washed with hot water containing a little ammonia. It is very necessary to redissolve the precipitate (chiefly ferric hydrate) even though usually it is very small as it always carries down some zinc with it. The solution is made up with hot water to about 750 cc., and is heated in a conical flask nearly to boiling. Half a test-tube full (about 10 cc.) of freshly made colourless ammoniac sulphide (NH₄HS*) is added, and the solution boiled for two or three minutes and allowed to settle. The boiling converts the slimy precipitate into a granular one. The flask is then covered and left to stand all night, the clear portion is syphoned off to just above the precipitate, and this portion, although having only a slight opalescence, is filtered through

a double filter of good Swedish filter-paper, and it is important that the filter exactly fits the funnel, and is held down in its place whilst it is moistened before use. The filter-paper used has a diameter of 5½ in., and the ash of one of these weighs 0.0015 grm., so that the tare for the two is 0.003 grm. After the deanted portion has been filtered, the precipitate is washed once by decantation with hot water containing a little ammonia chloride and a few drops of ammoniac sulphide. It is then transferred with hot water containing a few drops of (NH₄)HS to the filter, the filter being kept covered with a ground glass plate. The whole of the precipitate is very readily removed from the flask as it does not stick to the glass. The precipitate is then dried and transferred to a Rose's crucible, the filter being burnt in a separate crucible and the ash added to the precipitate; a little pure sulphur is added, and it is then ignited in a current of coal-gas, at first gently, and then for about five minutes in a large Bunsen flame; it is then allowed to cool in the current of coal-gas, and weighed.

The following results are those obtained from ordinary samples of blende (dressed ore from the mines); I. and II. duplicates of the same sample—

I.			II.		
Zinc.		Difference.	Zinc.		Difference.
Per Cent.	Per Cent.		Per Cent.	Per Cent.	
57.55	57.68	0.1	60.67	60.59	0.08
61.79	62.01	0.22	56.42	56.55	0.13
57.28	57.40	0.12	58.39	58.39	Nil
61.88	61.32	0.56	59.17	59.43	0.26
56.62	56.65	0.03	59.48	59.7	0.22
57.19	57.53	0.34	57.83	58.06	0.23
58.73	58.57	0.16	60.4	60.06	0.34
60.31	60.57	0.26	53.79	53.84	0.05
58.46	58.55	0.09	61.38	61.53	0.15

59.76	59.64	0.12	44.09	44.26	0.17
57.74	57.71	0.03	57.19	57.05	0.14
58.36	58.39	0.03	57.42	57.72	0.3
57.96	58.13	0.17	54.71	54.68	0.03
60.41	60.21	0.2	60.14	60.14	Nil
53.94	54.17	0.23	59.27	59.28	0.01
57.5	57.36	0.14	56.8	56.93	0.13
55.72	55.52	0.2	58.43	58.7	0.27
55.84	55.84	Nil	58.7	58.73	0.03
59.96	60.16	0.2	59.94	59.91	0.03
60.77	60.91	0.14	59.4	59.6	0.2
57.93	58.03	0.1	57.58	57.68	0.1
53.81	53.74	0.07	59.01	59.03	0.02

The above table contains 100 ordinary results from 50 different samples of blende, of these results 2 differ by 0.56 per cent., 6 differ from 0.3 to 0.34 per cent, 24 differ from 0.2 to 0.27 per cent., and the remaining 68 differ by less than 0.2 per cent., and 36 out of these 68 differ by less than 0.1 per cent.

If the ores contain manganese the process requires to be modified; the zinc can be precipitated as sulphide in an acetic acid solution, or the manganese can first be removed by precipitation with bromine.

* This will keep for about a week in the dark, but soon turns yellow in the light, especially in direct sunlight.

That the precipitation of zinc as sulphide is more accurate than the precipitation as carbonate is obvious by the fact that if to the filtrate from the carbonate a few drops of ammoniac sulphide are added, a few flakes of zinc sulphide will separate on standing a few hours, and Fresenius states that with proper precautions a solution containing only $\frac{1}{800,000}$ of zinc may be precipitated by ammoniac sulphide. An important objection to the precipitation of the zinc as carbonate is that these ores always contain lime, so that the sulphide must be carefully washed before it can be redissolved and precipitated as carbonate.

(b.) PRESENCE OF LEAD IN AMMONIA SOLUTION.

In preparing ammoniac sulphide I have found that it is not unusual for so-called pure ammonia to become brownish or black in colour on passing H_2S through it. This is due to traces of lead, and it is advisable to examine every fresh bottle before employing it. It is easy to obtain ammonia that is pure, but there is certainly a good deal sold that contains this impurity, and it is one that may very easily be overlooked. I have been informed that it is due to the dilution of the solution in leaden vessels, when first prepared, to the requisite specific gravity.

(c.) ASSAY OF GALENA IN IRON CRUCIBLES.

The most satisfactory method for the assay of galena is undoubtedly that in which the assay is made in wrought-iron crucibles. The usual method is to charge the assay from a scoop into the red-hot crucible, removed from the furnace for the purpose. It is then heated for about 15 minutes, the sides of the crucible scraped down with an iron rod, and the heat continued a little more strongly for five minutes. This is the method recommended by Phillips, and is identical with the one taught at the Royal School of Mines.

Makin states that the assay should only be in the furnace for about 10 minutes, but I find from a large number of assays made in different ways that the best results are obtained if the fusion is completed in about five minutes, the furnace being kept a little hotter than is usual. The assay should be watched, and as soon as it has run down and is tranquil, it should be taken out and poured, and as usual the pot tapped on the top of the furnace, and any shots poured into another mould. In this way I have had excellent results in as short a time as three minutes.

From well-dressed ores the material yields from 83 to 83.7 per cent of lead; by the longer method, the same samples will only yield about 82.5 per cent. These assays were from samples representing from 50 to 200 tons of ore, and not from small samples of pure galena.

(d.) USE OF THE ASSAY TON.

Having had some time ago to make a large number of assays of gold quartz, many which contained very small quantities of gold, it occurred to me that it would be simpler than taking percentage weights, and more reliable than tables, to take a weight that would give the number of grains of gold per ton direct.

Thus for poor ores, if 78.4 grms. are taken, and two assays are made, $\frac{1}{10}$ mgrm. from the two assays will represent 10 grains of gold per ton (1 ton contains 15,680,000 grains), and as a good bullion assay balance will indicate distinctly $\frac{1}{20}$ mgrm. if the above weight is taken, one can obtain results down to 5 grains per ton.

For ores containing over 5 dwf. of gold per ton, 39.2 grms. is a convenient weight, $\frac{1}{10}$ mgrm. (from one assay) being then equal to 40 grains per ton. For richer ores, 31.36 grms. can be taken, when $\frac{1}{10}$ mgrm. is equal to 50 grains per ton.

Somewhat similar weights are, I believe, used in America, under the name of "assay tons," but at the time I first used them I did not know this, and worked out the quantities myself.

(e.) ESTIMATION OF FREE AND ALBUMINOID AMMONIA IN WATER.

A good method for checking these results I find to be as follows:—

A larger retort than what is usually employed is taken, and after both free and albuminoid ammonia have been estimated, a duplicate portion of water is added to the residue in the retort, which is now absolutely free from ammonia, and the total ammonia is determined. This will always be identical with the free plus the albuminoid ammonia if the first results were correct.

(f.) ESTIMATION OF SMALL QUANTITIES OF IRON IN PRESENCE OF ALUMINA BY STANDARD PERMANGANATE.

For quantities of iron from 0.5 to 4 or 5 per cent., such as occur in clays, the precipitate of Al_2O_3 and Fe_2O_3 can be weighed together, and the precipitate afterwards dissolved in strong HCl in a flat-bottomed conical flask; moderately strong H_2SO_4 is then added, and the flask heated on an iron plate till all HCl is driven off. The residue is dissolved in water and reduced with a little zinc, and the solution titrated with $\text{K}_2\text{Mn}_2\text{O}_8$. Very good results are obtained.

DISCUSSION.

J. CARTER BELL said he had had a good deal to do with the estimation of zinc in various ways. Thirty years ago he estimated zinc by means of sulphide of sodium, but found it a most unsatisfactory process, as a great amount of practice was necessary to obtain good results. He had also tried the method suggested by Mr. Lowe, but he had always found a difficulty in the zinc coming down in the slimy state. He wished to know how long Mr. Lowe boiled the sulphide to get it into a granular condition, because the success of the method depended upon the time it took to filter. He found a day or a day and a half were required to filter it. He washed it by decantation, and then dissolved it in hydrochloric acid, and estimated it as carbonate of zinc. This could be filtered and washed in less than an hour.

MR. GRIMSHAW wished to know what was the average percentage of zinc in the list of 100 ores given in the paper?

MR. LOWE replied from 56 to 60 per cent.

MR. GRIMSHAW asked if Mr. Bell weighed the carbonate of zinc or washed it through the filter and titrated it?

MR. BELL said that he always weighed.

MR. LOWE, in reply to Mr. Carter Bell, said that five minutes good boil was quite sufficient to convert the sulphide of zinc from the slimy state to the granular.

SESSION 1891-92.

1892:—

March 5th.—Mr. Sidney Lupton. "Criticisms and Suggestions towards the Improvement of British Measures."

April 4th.—Mr. Thomas Fairley.

Meeting held at the Philosophical Hall, Leeds, Monday, February 1st, 1892.

DR. A. HESS IN THE CHAIR.

CONTRIBUTIONS TO THE ANALYSIS OF FATS. II. SPERM OIL.—WOOL-FAT.—CHOLESTERIN.

BY DR. J. LEWKOWITSCH.

IN the course of some research work I undertook in the laboratory whilst working out a technical process which I introduced into the works I am connected with, I had occasion to make some observations which may, perhaps, prove of some little use to chemists working in the same direction. Circumstances permit me only to give here incoherent notes and a few new observations which I had no time to pursue any further and round off in a satisfactory manner as I should have desired, for, unfortunately, a technical chemist has to break off research work just at the moment when it becomes highly interesting to the scientific chemist for the melancholy reason that "it does not pay." These prefatory remarks will have to excuse the scantiness and incoherence of the following notes.

In the course of my work the necessity arose of determining the nature and quantity of unsaponifiable matter in fats. The literature on that subject being very scanty, I had to look out for substances containing larger quantities of such unsaponifiable bodies and examine them myself. Suitable material for my purposes appeared to be sperm oil and wool-fat; the latter being difficult to obtain, I chose instead of it "recovered grease," or so-called "Yorkshire grease."

I.—SPERM OIL.

Sperm oil, the liquid part of the fatty substance found in the cavities of some whales, is known to contain higher alcohols of the aliphatic (*ἀλειφας*: fat) series. I prepared these alcohols in the usual way from sperm oil by saponifying a pure specimen of the latter by means of alcoholic potash, and obtained 41 per cent. of unsaponifiable substances. A preliminary experiment was made by distilling 50 gr. of the product in a vacuum of 24 in. The thermometer rose rapidly to 300 C., and the bulk distilled over between 300—305° C., representing on cooling a white crystalline mass melting between 22—30° C.

It is well known that the ethers of the alcohols and acids of the aliphatic series are easier to distil than the original bodies themselves, and that even the lower members can only be effectively separated by fractional distillation after they have been transformed into their ethers. It was

therefore thought that by converting the sperm oil alcohols into their acetates and by subsequent fractional distillation of these ethers, some separation might be effected. Of course, I did not and could not expect to arrive by this method at a complete or even approximate separation of bodies boiling at such high temperatures and apparently being so nearly related to each other. Anyone who is practically acquainted with the distillation of such high boiling substances as, *e.g.*, mineral oils or tar oils, will recognise at once the futility of such work, even if carried out with large quantities. At the outset I had, therefore, to give up every hope of obtaining substances the elementary analysis whereof might be undertaken with some result, but there appeared to be a chance of deriving more information from applying the methods used in the technical analysis of fats to the fractions (this Journal, 1890, p. 842).

I prepared the acetates by boiling 200 grms. of the mixture of alcohols with 300 grms. acetic anhydride in a flask connected with a reflux condenser for a couple of hours. The resulting product was freed from acetic acid and acetic anhydride by repeatedly heating it in vacuo up to a temperature of about 200° C. The mixture of acetates did not crystallise at the ordinary temperature, and therefore fractional distillation in vacuo was resorted to.

The distilling flask and adapter used have been described by me (Jour. Chem. Soc. 1889, 359), and it only remains to add that the flask was not heated over free fire, but immersed into an air-bath consisting of an iron dish, while a mantle of asbestos protected the flask against loss of heat. The acetates distilled very well indeed in a vacuum of 26 in., showing no signs of decomposition, which was proved by the excellent yield of the distillates and by the nature of the residue in the flask, for although dark in colour it gave, on examination, figures which stood in welcome correspondence to those of the distillates. The first fraction was put aside as possibly containing some acetic acid or acetic anhydride; in fact, it must have contained some, as the saponification value of it was very high, reaching as high a figure as 415. The distillates were collected in four fractions, the receivers being changed when the thermometer, which had appeared to remain constant for some time, began to rise, and when the distilled liquor seemed to possess another specific gravity. Thus I obtained in a vacuum of 26 in., between the temperature of 295° C. and 315° C., four fractions, which, on being saponified by means of standardised alcoholic potash, gave the following saponification values:—

Fraction.	Saponification Value.
1st	187.7
2nd	185.0
3rd	183.0
4th	168.0
Residue	159.5

The quantities of these four fractions did not differ considerably.

For the sake of comparison I subjoin the saponification values, which theory requires for the acetates of ethyl-alcohol and octadecylalcohol:—

Cetylacetate.....	197.5
Octadecylacetate.....	180.0

A second fractionation of the four fractions gave the following result (the first grm. or two were discarded as "first runnings") :—

Fraction.	Saponification Value.
1st	187.9
2nd	181.1
3rd	175.3
4th	163.7

The saponification value of the first fraction has not undergone any change, and although no definite conclusion can be derived from these figures, this much is clear, that Allen's* assertion that sperm oil contains alcohols of the composition indicated by the formula $C_{12}H_{26}O$ and $C_{13}H_{28}O$, as he has found by elementary analysis, is not borne out by my figures, for the acetates of dodecyl and pentadecyl alcohol have the saponification values 246 and 207.7 respectively. But to remove every doubt, a third fractionation was undertaken, although no further separation could reasonably be expected. The values, as found, are given here :—

Fraction.	Saponification Value.
1st	190.2
2nd	183.8
3rd	180.7
4th	174.4
Residue	161.4

Contrary to my expectation, these acetates were able to absorb iodine—a fact which Allen has already recorded for one specimen of sperm oil—and therefore the supposition that the alcohols consisted mainly of a mixture of cetyl alcohol and octodecyl alcohol, and some higher homologues thereof, had to be abandoned.

In order to prepare the alcohols themselves the acetates were saponified by means of alcoholic potash, the separated alcohols washed free from potash, and finally filtered in a drying oven. All the alcohols solidified on cooling.

Their iodine absorption values were found as follows :—

Fraction.	Iodine Absorption.
	Per Cent.
1st	46.18
2nd	63.3
3rd	69.8
4th	81.8
Residue	84.9

These figures clearly show that the alcohols, or, any way, large percentages thereof, belong to alcohols of the unsaturated series. For comparison's sake I add the saponification and iodine values of the following *unknown* alcohols of the ethylene series :—

Formula.	Saponific Value of the Acetates.	Iodine Value.
		Per Cent.
$C_{16}H_{32}O$	199	106.6
$C_{18}H_{36}O$	189	94.8
$C_{20}H_{40}O$	166	85.8

The presence of an alcohol of the formula $C_{15}H_{30}O$ (see Allen, *Comm. Org. Analys.* II., 170), seems to be excluded, but it remains open to doubt, whether alcohols of the series $C_nH_{2n-2}O$, may not be present. The higher alcohols of the ethylene and the acetylene series are hardly known. Sperm oil being a comparatively cheap raw material and at the same time easy to obtain, this subject seems only to be awaiting further research in order to fill up some of the gaps in the series of alcohols belonging to the aliphatic group. The occasion appeared, however, too tempting to leave off here, although time forbade to enter fully into the investigation, and therefore only three

experiments were carried out with some of the alcohols, which, I am sorry to say, did not yield any definite result on the first attack and had therefore to be abandoned.

Alcohols belonging to the series, $C_nH_{2n}O$, and therefore containing a $CH=CH$ group should, when acted upon by a mild oxidising agent, become transformed into an alcohol of the glycerol series, as has been shown by Wagner* who actually prepared glycerol from allyl alcohol by oxidising the latter with a 1–5 per cent. solution of potash permanganate. I tried to oxidise in this way 30 grms. of the alcohol fraction No. 4 (absorbing 81.8 per cent. iodine solution), adding the calculated quantity of a 3 per cent. permanganate and finally warming gently on the water-bath, until all the permanganate was used up. The solution was distilled down by means of steam passed through it and afterwards freed from the precipitate of manganese by filtration. The filtrate was concentrated to 300 cc. in a flask connected with a condenser. Along with the water a white flocculent substance passed over which was obtained in too small a quantity to allow any further examination. The distilled liquid did not reduce silver nitrate on boiling. The 300 cc. were treated with carbonic dioxide, boiled down until salt began to crystallise and finally extracted with a mixture of ether and alcohol. On evaporating the solvent I obtained 16 grms. of a liquid, solidifying on cooling to a crystalline mass. The iodine absorption value of this substance was 71.3, thus showing that of the obtained 50 per cent. a small quantity only could have been transformed into a product of the glycerol series.

A second quantity of the alcohols was dissolved in glacial acetic acid and bromine dissolved in the same menstruum added, until the bromine was no longer absorbed; it was hoped that a crystallising bromine-derivative might be obtained. As no crystals separated from the acetic acid solution, the acid was removed by washing with water and the substance dried by washing with alcohol and subsequently with ether. No crystals having been obtained, it was tried to distil the oily substance, but it was found impossible to carry this out, as at about 160° C. large quantities of hydrobromic acid were given off, pointing to a decomposition of the substance.

A third quantity of the alcohols was heated with potash lime in order to convert, if possible, the alcohol into the corresponding acid. A far larger quantity of hydrogen was evolved than theory would require for the formation of the expected acid, and on extracting from the potash lime the supposed potash salt by means of water and acidulating with hydrochloric acid, only a very small quantity of insoluble fatty acid was obtained. The acid solution was therefore exhausted with ether, when I obtained 0.374 gm. of an oily acid requiring 2.1 cc. per cent. of normal potash for neutralisation. It would not be permissible to calculate the molecular weight from a titration of this small amount. The exhausted aqueous solution seemed to contain a dibasic acid. The undissolved lime contained besides some unchanged alcohol, the lime salt of an organic acid.

It is evident that no value must be attached to these last-mentioned experiments, as they hardly constitute more than the very first steps towards the examination of these interesting alcohols.

II.—RECOVERED GREASE.

The "recovered grease," on which the following observations were made, was mainly a so-called "Yorkshire grease," a fat recovered from the soapsuds used in wool scouring; other samples, obtained from continental works, were also examined, but only for the purpose of controlling the methods adhibited.

The constituents of such a recovered fat would naturally and most conveniently be classified under the following three heads :—

(1) Free fatty acids, resulting from the decomposition of the waste soap by means of a mineral acid and partly owing their presence to the existence of free fatty acids, peculiar to the wool-fat, as has been shown by E. Schulze,

* Commercial Organic Analysis, Vol. II., p. 169.

* Berichte der deutschen chemischen Gesellschaft **21**, 1230, 3343, and Ref. 182.

whose three papers in the *Berichte der deutschen chemischen Gesellschaft* V. 1076, VI. 251, VII. 571, are the most valuable contributions to the chemistry of wool-fat.

(2.) Neutral, *i.e.* saponifiable fats. These are the real saponifiable constituents of wool-fat, the cholesteryl ethers and other ethers of fatty acids, *e.g.*, ceryl cerotate. Mixed with these characteristic bodies there may be present some glycerides, remainders of the oil that has been used in oiling the wool. Some text-books quote amongst the constituents of wool-fat the glycerides of lower fatty acids, but I was unable to find the original source in the literature, whilst Schulze distinctly states that no glycerol has been found in the wool fat examined by Hartmann (*cfr.* *Berichte* V. 1075, footnote). I may state here at once that I did not find any glycerol in the samples of recovered grease I examined.

(3.) Unsaponifiable matter, under which head we may comprise free alcohols, *e.g.*, cholesterol and ischolesterol, as characteristic for the wool-fat, and besides these, hydrocarbons, coming from oils used in greasing wool, which may have been adulterated with (or "improved" by, as some will have it) a smaller or larger quantity of mineral oil.

If we accept this classification as correct, a convenient method for separating these three classes of substances seems to be naturally given.

The free fatty acids would have to be eliminated first, by converting them into their soda soaps and separating these from the substances of classes 2 and 3.

The amount of alkali required was first ascertained by careful titration of smaller quantities and the greatest part of the caustic soda necessary for a weighed larger quantity, which had been previously dissolved in alcohol, added and titrated with half-normal alkali, until the solution became pink to phenolphthalein. A good deal of the neutral fats and unsaponifiable matter rose to the top as an oily layer and was thus separated from the soap solution, whilst a smaller quantity remained suspended in the latter. The oily layer was dissolved in ether and the soap solution repeatedly shaken out with ether. The ethereal extracts were united with the main quantity and the ethereal solution washed with water to remove the last traces of adhering soap. Although apparently simple, this process requires more than ordinary patience, because only too often emulsions are formed, and unfortunately at the last stages, which seem to defy any attempt to separate them into two layers. Allowing to settle out for a period of several weeks proved of no avail, and the last resource was to deal with the ethereal solution in small quantities, and to treat them alternately with a diluted solution of caustic soda, or with diluted alcohol and so on. Another source of trouble was the appearance of an intermediate layer between the ethereal solution and the soap solution. It was separated best by throwing it on a filter. This flocculent stratum was found later on to consist of a soap formed by a higher* fatty acid, which soap was not soluble in water but dissolved readily in the boiling alkaline solution of the other fatty acids.

Thus the free fatty acids were obtained in two parts: firstly the fatty acids of the dissolved soaps, and secondly those of the difficultly-soluble solid soaps. The ether dissolved in the soap solution was distilled off and finally the fatty acids set free by acidulating the liquor with hydrochloric acid. The fatty acids were washed until the washwaters were free from acid, separated from any water, and filtered in a drying oven. It will thus be seen that no attention was paid at this stage to the presence of any volatile, soluble, fatty acids, and this course was adopted throughout this examination—except for the ultimate analysis of this recovered grease, which will be found below. It may be further pointed out at once that all the substances have been dried and filtered before being examined.

Weighed quantities of the fatty acids recovered from the soap solution were dissolved in dilute alcohol and titrated with aqueous half-normal soda for the determination of their molecular weight. I found in three experiments 376, 378, 379, therefore the means 377.6. Later on in the

course of my research I noticed that some of the higher fatty acids very easily underwent an appreciable loss in the drying oven at a temperature not exceeding 100° C., pointing to the formation of anhydrides or possibly lactones, which manifested itself in a very high molecular weight being found; for these anhydrides behaved during the titration with aqueous caustic soda, so to speak, as an inert mass, not being hydrolysed by aqueous alkali, or, any way, not completely (this *Journal*, 1890, 846). That this was so, was easily proved by titrating with alcoholic potash, which would hydrolyse any anhydrides formed and consequently, the full amount of caustic being found, reduce the molecular weight to its proper value. The fatty acids, found above to possess the mean molecular weight 377.6, were therefore boiled with standardised alcoholic potash and gave now the molecular weight 327.7 and 326, wherefrom the means 326.8 may be derived as the true mean molecular weight. The solid soap which was obtained as an intermediate layer between the ethereal and aqueous solutions and had been collected on a filter, was treated with boiling water and hydrochloric acid, and thus the fatty acids were set free. Their molecular weight was found by titration with aqueous soda something like 3,920, which of course is absurd; boiled with standardised alcoholic potash they gave, on titrating back the excess of caustic potash, the molecular weight 520, as the means of two agreeing determinations. These fatty acids are very difficultly soluble in alcohol. The proportion of the free fatty acids forming easily soluble soaps to the free fatty acids, giving the solid soaps was as 9:1; the mean molecular weight of all free fatty acids may therefore be assumed to be $\frac{9 \times 326 + 520}{10} = 345$.

The free fatty acids from the soap solution were found to possess a higher molecular weight than was expected; the supposition that the higher free fatty acids peculiar to the wool-fat would be solely contained in the solid soap not having been borne out by the facts. An easy method for separating the fatty acids possessing a molecular weight above 280 from those of about 280 (stearic and oleic acid) seemed to be given by the observation contained in a patent of the *Norddeutsche Wollkammerei und Kammgarne-Spinnerei zu Bremen* (D. R. Pat. 55,110, December 3, 1889), that the soaps of the former acids are only soluble in hot alcohol and separate out on cooling the solution below 25° C., whilst the soaps of the latter fatty acids are soluble both in hot and cold alcohol. Therefore 50 grms. of the fatty acids recovered from the soap solution were dissolved in hot alcohol and titrated with alcoholic soda until neutral. Sufficient alcohol was added to hold the soaps easily in solution whilst warm, and then allowed to cool below 25° C. The soap deposited on cooling was separated by filtering and sucking off the mother-liquor, and subsequently the fatty acids of both the solid and the dissolved soaps were prepared and titrated in order to determine their molecular weights. The estimation by means of aqueous soda gave, for the acids of the solid soap, the mean molecular weight 343, while the fatty acids of the dissolved soap gave 394. When using alcoholic potash, as was necessary after the above-mentioned experience, I found the respective molecular weights, 303 and 338. The fatty acids of the molecular weight 303 were solid, those possessing the mean molecular weight 338 were liquid, which appeared at first surprising, but may find an explanation by the assumption that the liquid acids belonged to an unsaturated series.

It will be evident that the method of separating the sodium salts of the fatty acids by means of alcohol would require a tedious repetition of the same operation without, however, apparently possessing an advantage over the older equally tedious methods.

The higher fatty acids of the molecular weight 520 offered a special interest both on account of their high molecular weight and their property of easily losing water. It was easy to decide whether the normal anhydrides or lactones, *i.e.*, inner anhydrides, were formed. I have shown that on boiling fatty acids which possess the COOH group only, and no OH group besides, with acetic anhydride (this *Journal*, 1890, 843) the normal anhydrides are formed, and this can be easily ascertained by weighing the resulting product, for *e.g.*, $2 C_{15}H_{31}COOH$ being transformed by

* Under "higher" fatty acid I shall understand throughout this paper fatty acids possessing a molecular weight above 300.

that reagent into $(C_{15}H_{31}CO)_2O$, will lose one molecule of water. Hydroxylated acids, e.g., $C_{15}H_{31}(OH)COOH$, will, as far as the $COOH$ is concerned, undergo the same change, but the hydrogen atom of the OH group will at the same time be exchanged for an acetyl group and the resulting product, $[C_{15}H_{31}(OC_2H_5O)CO]_2O$, will, on weighing, show an increase, the loss of H_2O by two molecules of the acid being more than counterbalanced by the taking up of two C_2H_5O groups. I boiled, therefore, 5·9283 grms. of the fatty acids, molecular weight 520, with acetic anhydride, and obtained on a weighed filter 6·1960 grms., i.e., an increase of 4·52 per cent.; it was, therefore, evident that they contained to a large extent hydroxylated acids. A pure hydroxylated acid of the molecular weight 520 would, by the same operation, increase by 6·5 per cent. The iodine value of these fatty acids was 21·5, but from this no conclusion as to the series the acids or part of them belong to, can be drawn. One more point had to be decided by experiment, viz., whether the higher acids of the series, $C_nH_{2n+1}O_2$, easily lose water with formation of anhydrides. As I possessed a pure specimen of cerotic acid—molecular weight 410—I examined it in this respect. 5 grms. were heated to 130° C., dissolved in alcohol and titrated with aqueous half-normal soda. The molecular weight was found 415, so no anhydration has taken place.

The Neutral Fat and the Unsaponifiable Matter of the recovered grease were contained in the ethereal solution after the free fatty acids had been removed, and both were obtained together by distilling off the solvent. The substances one might expect to find in this part of the grease have been already enumerated above. The absence of glycerol, and consequently of glycerides, was proved by completely saponifying a larger quantity of the recovered grease and examining the aqueous solution. Hydrocarbons, or, to be more correct, appreciable quantities thereof, could not be present, as the substances extracted by ether after such a complete saponification of the recovered grease were completely dissolved by acetic anhydride without separating any mineral oil on cooling. The unsaponifiable matter would therefore most likely consist of cholesterol, ischolesterol, and perhaps other alcohols. To separate the latter from the neutral fat the mixture of both was repeatedly extracted with boiling alcohol, in which, as Berthelot has shown, the cholesteric ethers are nearly insoluble. That part, however, of them, which dissolved in the boiling liquid, separated on slight cooling as an amorphous mass, and although it was apparently identical with the insoluble substance, it was still kept separate, so as to ensure my having to deal with a substance free from any unsaponifiable matter. The extracted part will be spoken of later on, here the neutral fat only will be considered. This neutral fat is a viscous, wax-like substance, melting into a thick liquid when moderately heated. No doubt this substance is very similar to that part of Schulze's wool-fat which proved insoluble in alcohol and yielded to him on saponification cholesterol and ischolesterol, but with this important difference, that my substance is a neutral body, whilst that of Schulze, in the case of some specimens of wool-fat, contained free fatty acids, which, as stated above, are difficultly soluble in alcohol. For further examination this neutral fat had to be saponified, and to gain at the same time some insight into the nature of the unsaponifiable matter contained in the "recovered grease," the neutral fat was analysed alongside with the mixture of saponifiable fat and unsaponifiable matter, as obtained direct from the ethereal solution described above. The saponification of this neutral fat does not take place readily even when using a large excess of alcoholic potash and heating over free fire for an hour; the discordant figures which were obtained in parallel experiments showing that saponification had not been completed in every case. Satisfactory results were at last obtained when the saponification was carried out with alcoholic double normal potash under pressure. The use of a copper bottle, as shown in the diagram, was found very convenient for this purpose; the bottle was immersed into boiling water for an hour or so and the contents shaken up from time to time. Some time after I had finished these experiments a patent was taken out by Kossel and Obermüller (D.R. Pat. 55,057) for the saponification of fats by means of metallic sodium thrown

into a mixture of fat and absolute alcohol, or, what amounts to the same, by means of sodium alcoholate. I compared this method with the one I practised myself quantitatively, using of course a freshly-prepared solution of sodium alcoholate, as this could be titrated. The figures show an absolute correspondence between the two methods:—

1 grm. of	Requires of	
	Alcoholic Potash under pressure	Sodium Alcoholate.
	quantities corresponding to	
A. Neutral fat	1·825 cc. 1/1 KOH	1·825 cc. 1/1 KOH
B. Neutral fat + Unsaponifiable.....	1·733 cc. 1/1 KOH	1·727 cc. 1/1 KOH

Although more expedient, Kossel and Obermüller's method may be found a little too costly in the practice of the analytical chemist, and it is much to be feared that for the same reason the patentees may not find any manufacturer who will take a licence from them for saponifying glycerides—or even wool-fat—by means of metallic sodium and absolute alcohol.

The saponified fats were shaken out with ether to extract the alcohols (in case of B. the alcohols and unsaponifiable matter), and the exhausted soap solutions acidulated with hydrochloric acid. The separated acids were washed on a tared filter and weighed as in Hehner's method of the analysis of butter.

The following figures were obtained:—

	A. Neutral Fat.		B. Neutral Fat + Unsaponifiable.	
	I.	II.	I.	II.
Fatty acids	Per Cent. 56·3	Per Cent. 54·1	Per Cent. 50·7	Per Cent. 49·8
Alcohols	43·2	44·0	47·5	47·6
	99·5	98·1	98·2	97·4

The sum of the analyses does not come up to 100 per cent., although it was expected that the sum would be 102 per cent. to 103 per cent., as 2 to 3 per cent. of water have been taken up during saponification. The error can only be looked for in the figures for the fatty acids, and it was therefore impossible to calculate the molecular weight of these fatty acids from their weight and the quantity of normal potash used during saponification. That the figures for the fatty acids have been found too low may be partly accounted for by the above stated observation that the wool-fat acids lost some water during the operation of drying, or, in other words, through the fact that during the drying, anhydrides or lactones, or both, may have been formed. The latter opinion was sufficiently supported by the difference of the figures found for the molecular weights of these fatty acids, when these weights were determined both by means of aqueous half-normal soda and alcoholic potash. The titration with aqueous soda gave the molecular weight 363, whilst on using alcoholic standard solution the values found were 325 and 330, means 327·5. The latter value has to be considered as the correct one. It hardly needs mentioning that the fatty acids of A. and B. were identical.

By means of the values obtained for the molecular weight for the alcohols, and the amount of alkali used during saponification, it is possible to calculate the composition of A. and B.

	A. Neutral Fat.	B. Neutral Fat + Unsaponifiable.
Alcohols (means)	43.60	47.55
Fatty acids {	1.825 x 327.5	59.77
	1.73 x 327.5	..
	..	56.66
	103.37	104.21

These figures may be accepted as fairly representing the two constituents of A. and B. after they have undergone hydrolysis.

The analysis of the neutral fat gives us the means of calculating the mean molecular weight of the *alcohols* by means of the equation $M = \frac{13.6 \times 327.5}{59.77} = 239$. The same analysis also allows us to calculate the quantity of unsaponifiable matter, *i.e.*, free alcohol in the part B; for the 56.66 per cent. fatty acids of this part require for the mean molecular weight 239 of the alcohols, 41.34 per cent. alcohol to form neutral fat. (The same figure can be calculated more quickly from the proportion 59.77:43.60 = 56.66:x.) Consequently part B contained 47.55 - 41.34 = 6.21 per cent. free alcohols. Of course, this estimation has to be taken "cum grano salis," but analyses of this kind have to be supplemented to some extent by calculations which keep within permissible limits.

The fatty acids absorbed 17 per cent. iodine only, which excludes a larger quantity of unsaturated acids.

The fatty acids were not examined any further. The alcohols were boiled with twice their weight of acetic anhydride to transform them into their acetates; weighed quantities were used, and the increases in weight, the alcohols, acquired, were determined by collecting the resulting products on weighed filters, when the following figures were obtained:—

	Weight of Alcohol.	Weight of Acetate.	Increase.	Means.
	Grms.	Grms.	Per Cent.	Per Cent.
Neutral fat {	4.4574	5.9084	12.35	12.7
	7.7967	8.8149	13.06	
Neutral fat + } unsaponifiable {	6.024	6.8624	13.9	13.6
	7.077	8.0202	13.3	

For the sake of comparison I add the corresponding values (*i.e.*, the increase due to the exchange of one atom of hydrogen for an acetyl group) for several alcohols:—

Alcohol.	Increase.
	Per Cent.
Cetylalcohol.....	17.2
Cerylalcohol.....	10.6
Cholesterol or Isochol.....	11.3

The saponification values of the acetates obtained were determined next, as experiments mentioned below showed how tedious and comparatively useless it was to try to separate the acetates by crystallisation from alcohol. As will be seen in the third part of this paper a separation of cholesterol from cetylalcohol may be undertaken with some success by this method, but the higher aliphatic alcohols—and these were present to all appearances—yield oily liquids which could not be brought to crystallisation. The following figures were obtained:—

Acetates from Alcohols of	Weight.	Alcohol 1.1 KOH used for Saponifying.	Saponification Value.
	Grms.	cc.	
A. Neutral fat.....	8.5720	24.53	160.9
B. Neutral fat and unsaponifiable	17.3226	20.40	156.3

For the above-mentioned three alcohols we arrive at the following theoretical saponification values of their acetates:—

Acetate of	Saponification Value.
Cetylalcohol.....	197.5
Cerylalcohol.....	128.0
Cholesterol or Isochol.....	135.6

The corresponding values for octylalcohol, which Guetta states to have found in the distillates of wool-fat, is 330. I have not tabulated this alcohol along with the others, as Hannau* could not prove its existence in distilled wool-fat.

I prepared about 20 grms. of the alcohols from the neutral fat A, in the hope of isolating the cholesterol by crystallisation from ordinary alcohol or a mixture of alcohol and ether (a corresponding experiment carried out with the acetates of these alcohols will be described further on), but I discovered soon that it was impossible to arrive at satisfactory results in this way—anyhow, in the limited time at my disposal. Other solvents, like chloroform, petroleum spirit, benzene, did not prove of greater use. I obtained the same half-jelly-like, half-crystalline substances which Schulze described, and from which he successfully separated cholesterol and isocholesterol by means of their benzoates, while another alcohol which was present could not be identified by him. I had to give up any further attempts to isolate from the mixture of the alcohols any chemical individuals, and had recourse to the makeshift of colour reactions. I shall speak about these colour reactions in the third part of my paper, and shall therefore content myself here with stating that the colour reaction quite recently proposed by Schulze for isocholesterol (*Zeits. f. physiolog. Chem.* 14, 522) was obtained with very satisfactory sharpness, whilst the corresponding reaction for cholesterol could not be obtained, but this by no means excludes the presence of cholesterol.

The amount of *unsaponifiable matter*, judging from the analysis of the part B. (mixture of neutral fat and unsaponifiable) could be a very small one only; it has been calculated above as 6.21 per cent. of part B. As mentioned above, this third class of the constituents of the recovered grease had been obtained in the course of the preparation of the neutral fat, and was contained in the alcohol which had been used to effect the separation.

Whilst writing these lines I notice that Liebreich recently (*Arch. f. Physiol.* 1890, 363) proposed for the separation of cholesterol from cholesteryl ethers two reagents not very commonly met with, *viz.*: ethylaceto-acetate and ethyl-ethylaceto-acetate.

Mineral oil, to repeat this, which would have been extracted along with any free alcohols by the boiling alcohol, was not found as the solubility of the extracted mass in acetic anhydride proved. Consequently, I only expected to find cholesterol and isocholesterol. On cooling the alcoholic solution small crystals were obtained, which after being crystallised several times from that solvent seemed pure enough for examination. The melting point was found at 37°–58° C., consequently the crystals were neither cholesterol or isocholesterol. Moreover, on boiling the alcohol with acetic anhydride 108 per cent. of the original quantity was obtained as an amorphous substance melting between 37° and 39° C. The substance showed

* Public del Laboratorio Chimico Centrale delle Gabelle. Roma, 1891.

the ischolesterol reaction only very faintly and absorbed 3.7 per cent. iodine only. It is therefore safe to conclude that the isolated alcohol is cerylalcohol, the presence of which in wool-fat (as the cerotate) has been stated by Buisine.

The mother-liquors from that cerylalcohol yielded gelatinous and finally oily substances, which could not be identified any further than by colour reactions, which spoke very distinctly for the presence of ischolesterol.

In the hope of arriving perhaps at better results as far as the alcohols were concerned, a larger quantity of the original recovered grease was saponified and the soap solution at once extracted with ether. Here again a large quantity of the intermediate stratum was obtained and collected separately in some experiments, so that all the fatty acids contained in the recovered grease—both the free and the combined acids—were, so to speak, fractionated to some extent; in other experiments all the fatty acids of the recovered grease were obtained in one mass by dissolving the intermediate layer in the hot soap solution and acidulating the latter.

The molecular weight of all the fatty acids, as prepared in the last instance, was found by titration with aqueous half normal soda: (1) 411.5; (2) 412; (3) 410.8; (4) 400; the determination by means of alcoholic potash, however, gave the values 331 and 333, so that 332 must be assumed as the true mean molecular weight of all the fatty acids of the recovered grease (regardless of any volatile acids).

The two fractions of the fatty acids—if I may say so—i.e.: (a) the fatty acids of the easily soluble soaps; and (b) the fatty acids of the intermediate stratum were also titrated separately for their molecular weight, with the following result:—

FRACTION A.

Molecular weight by titration with aqueous soda.....	340
Molecular weight by titration with alcoholic potash ..	318

It was tried to further fractionate these fatty acids by means of the above-mentioned patented method; in this instance also the solid fatty acids, forming the less soluble soaps, showed a lower molecular weight than the liquid acids, the sodium salts whereof were soluble in alcohol below 25° C. The figures obtained for the molecular weights were—

1.—SOLID ACIDS.

(a) by means of aqueous soda.....	323
(β) by means of alcoholic potash	309

2.—LIQUID ACIDS.

(a) with aqueous soda.....	385
(β) with alcoholic potash.....	331

FRACTION B.

Molecular weight by titration with aqueous soda.....	670
--	-----

The determination by means of alcoholic potash had not been carried out, as at that time I was not yet aware of the fact, that the higher fatty acids of the recovered grease underwent some sort of anhydration when subjected to a temperature of 100° C. The separation of these acids—or rather of their soaps—by means of alcohol into two fractions yielded a very small quantity of liquid acids only, the mean molecular whereof was found by means of aqueous soda 1380, and by means of alcoholic potash 618, whilst the greatest part consisted of solid fatty acids of the mean molecular weight 660 with aqueous soda, and 483 with alcoholic potash. The latter contained hydroxylated acids, for on boiling with acetic anhydride an increase of 3.3 per cent. was found. Their iodine value was only 8.9.

The alcohols were prepared in either case by shaking the soap solution repeatedly with ether, regardless of the middle layer which, in this case, gave far less trouble than the corresponding separation of the neutral fat and saponifiable matter from the free fatty acids. Quantitative experiments showed me that—notwithstanding the troublesome middle layer, the filtering off of which is by far the best

way of dealing with it—the extraction of the aqueous solution by means of ether and subsequent washing of the ethereal solution with water gives the best and most reliable result. The extraction of the dried saponified mass, mixed with sand, in a Soxhlet tube caused more delay, as, owing to the large quantity of unsaponifiable matter, the ether dissolved larger quantities of soap, which had to be eliminated by renewed washing. The substitution of petroleum spirit for ether in the last method gives worse results still, as it is well known that petroleum spirit, when a large quantity of unsaponifiable matter is present, dissolves notable quantities of soap. At that juncture I may point out that Hösig and Spitz (Zeitschr. f. angewandte Chemie, 1891, 565) propose, for the quantitative estimation of unsaponifiable substance, the extraction of the aqueous soap solution by means of petroleum spirit and the washing of the latter with 50 per cent. alcohol.

The extracted alcohols gave, on being incinerated, no ash, a test which should never be omitted in the quantitative estimations of such-like substances. The alcohols were dried, boiled with twice their weight of acetic anhydride, and the resulting acetates washed until free from acetic acid and dried. The increase of weight was determined quantitatively in two experiments as 9.90 per cent. and 10.2 per cent. The saponification value of the mixed acetates was found to be 150.6 (means of 149.9 and 151.3); their iodine absorption value was 44.03. The acetates were divided into two parts. The first part—about 90 grms.—was fractionated in vacuo in the same way as the acetates of the sperm oil alcohols. The temperature rose quickly to 330° C.—in a vacuum of 26 in.—and between 330 and about 350° C. three fractions were obtained, all of which possessed in a very marked degree that peculiar smell which is so characteristic of the high-boiling fractions of mineral oils. From these distillates seemed to separate crystals embedded in a viscous mass. I subjoin the saponification and iodine values of the three fractions; the first fraction may still have contained a little acetic acid, judging from its high saponification value. The residue was lost:—

Fraction.	Solubility in Alcohol.	Saponification Value.	Iodine Absorption.
1st.....	Easily soluble	237.5 (1)	Per Cent. 32.2
2nd.....	Not easily soluble.	136.5	57.0
3rd.....	Difficultly soluble	59.3	78.3

The difference of the solubility of these three fractions in alcohols may be considered as a fair indication of the decomposition that evidently took place. Fraction 3 contained the largest amount of hydrocarbons. It can therefore only be looked upon as a chance that the values found for the second fraction agreed very well with those which cholesterol and ischolesterol would give, viz., 135.5 and 68.3 (see Third Part of this paper). On trying to separate any cholesteryl acetate or ischolesteryl acetate from the second fraction by crystallisation from alcohol, only floes were obtained, while the greater part separated as a heavy oil. After a great many vain efforts to obtain crystals, the whole mass was saponified to prepare the alcohols from it, in the hope that the latter might be more easily identified. On crystallising them from a mixture of ether and alcohol I obtained a half crystalline mass, which showed very distinctly the reaction of cholesterol, besides that of ischolesterol. I am inclined to believe (see Third Part of this paper) that cholesterol was present in a larger proportion than ischolesterol. A determination of iodine values would, of course, have been of no use. Schulze's method of separation by means of benzoic anhydride could not be carried out both for want of time and of the apparatus required for heating the sealed tubes. But even this method would not have furnished satisfactory quantitative results. The two other fractions of the acetates—the first and the third—were treated in the same way. From the alcohols of the first fraction I obtained crystals which gave

the reactions for cholesterol and ischolesterol. The third fraction gave, on saponification, an oily mass, gelatinising on cooling, and evidently containing a larger quantity of hydrocarbons. Colour reactions of the kind described could not give any result with such a mixture.

It was tried to break up the second part of the crude acetates into its constituents by crystallisation from absolute alcohol, as cholesteryl acetate is known to separate in characteristic crystals from it. I started with 100 grms. substance. I obtained on cooling some crystals, but the by far greatest part separated as an oily viscous mass. It would be too long to describe at any length the most tedious trials to obtain the crystals in a pure form and larger quantity. Just when they appeared pure and were only once more dissolved to take away the last traces of the adhering oily substance, as I thought, a larger quantity of the oil would separate, and thus cause a fresh repetition of the series of crystallisations and recrystallisations. To cut it short, I at last succeeded in obtaining 7 grms. of the crystallised acetate, which, on redissolving in alcohol, did not yield any more an oily substance, while the remaining 93 per cent. were brought into one lot; for although part of it seemed to have a tendency of crystallising, it was impossible to differentiate the oil into several parts.

The crystalline acetate melted, on drying in the oven, below 80°C ., and so it was conjectured that it consisted mainly of a mixture of cholesteryl- and ischolesteryl-acetates which, according to Schulze, melts below 100°C ., but the saponification value found at 161 showed that I was yet far from having the pure substances. The alcohols contained in the acetates were therefore prepared, and on dissolving them in a mixture of alcohol and ether I obtained on cooling an indistinctly-crystallised substance which showed the ischolesterol reaction most beautifully, whilst the cholesterol reaction was only occasionally noticed. The determination of the iodine absorption of the alcohols (see Third Part of this paper) could definitively settle the question whether larger quantities of the cholesterins were present. The alcohols absorbed only 5.1 per cent.; this shows that by far the greatest part consisted of an alcohol of the series $\text{C}_{27}\text{H}_{52}+\text{O}$ and, as I had found previously cerylalcohol, this mixture of alcohols has to be considered as consisting of cerylalcohol, ischolesterol, and cholesterol.

The oily acetates gave saponification values lying between 106 and 106.5; the alcohol from these acetates increased on boiling with acetic anhydride by 7.6 per cent., as found in two experiments. From the saponification values, we may calculate, assuming for a moment a homogeneous substance, the molecular weight 528 for the alcohol, for which again we should find the increase, on acetylating, 7.5 per cent. But these oily acetates undoubtedly contained cholesteryl- and ischolesteryl-acetate, and their quantity might be approximately determined by the iodine absorption of the acetates, providing the other alcohols be saturated alcohols, an assumption for which the presence of cerylalcohol is only slender support. The oily acetates absorbed 31.99 per cent. iodine, whilst theory would require for cholesteryl- and ischolesteryl-alcohol (see Third Part of this paper): 61.3 per cent. We may therefore assume, in round figures, that the oily acetates contained 50 per cent. of the cholesterol acetates; as the saponification value of the latter is 135.5, the remaining 50 per cent. of the acetates would have to possess the saponification value of 77.5, which again leads, for the above assumption, to an alcohol of the molecular weight 724, or, roughly speaking, to an alcohol of the formula $\text{C}_{32}\text{H}_{64}\text{O}$.

But I must break off here, as such calculations rest on too unsafe a ground, and it may justly be objected that they are nothing but "jeu de nombres."

The examination of the alcohols contained in the recovered grease has therefore not revealed any new fact, except perhaps that I proved the presence of free ceryl-alcohol in it.

The free fatty acids of the recovered grease, and consequently of the wool-fat, are composed to some extent of acids having a molecular weight of over 400 and 500. These fatty acids, or some of them, are characterised by their tendency of easily losing water, thereby being transformed into lactones or inner anhydrides. This property

of the acids, due to the presence of hydroxylated acids, has not been noticed before, and therefore the high molecular weights, which, for instance, Allen quotes for the free acids of lanoline (*Comm. Org. Anal.* Vol. II., 317) as 570.9, or which I calculate from a titration, given in the above-mentioned German patent (100 grms. acids require 122 cc. 1.1 normal NaOH) as 820, must be considered as inadmissible.

The neutral fat of the recovered grease, which is the chief constituent of wool-fat, contains amongst other not identified alcohols: cholesterol and ischolesterol. Buisine has stated the presence of ceryl cerotate and consequently of ceryl-alcohol in this part of the wool-fat; but the method he adopted (*Bulletin de la Société chimique*, 1887, 72, 201), does not place this beyond doubt. Buisine saponified the wool-fat completely, and found amongst the alcohols ceryl alcohol, whilst he isolated from the fatty acids the cerotic acid. I have shown above that cerylalcohol occurs in the free state in wool-fat. The analysis of this neutral fat led us to the molecular weight 239 for all the alcohols; as cholesterol and ischolesterol possess the molecular weight 372, we are forced to assume the presence of lower alcohols in the neutral fat. Buisine arrives at the same conclusion from his experiments; he thinks they are lower homologues of cerylalcohol, but he has not isolated chemical individuals. Guetta's opinion that octylalcohol occurs in wool-fat is not necessarily invalidated by Ilanau's remark, that he could not detect it in distilled grease (see below). The fatty acids of this neutral fat share with some of the free fatty acids the property of easily forming lactones or inner anhydrides; consequently they contain hydroxylated fatty acids what has been further proved by the increase of weight on boiling with acetic anhydride. It is generally assumed and stated by text-books that the fatty acids of the wool-fat are essentially stearic and oleic acid, to which Buisine, accepting their presence, has added cerotic acid. I am of the opinion that this statement rests mainly on the resemblance the neutral fat bears to the cholesteryl-oleate and stearate, which Berthelot prepared synthetically, and further on Schulze's authority, I believe. But the latter simply bases his opinion that the cholesteryl and ischolesteryl oleates and stearates are present, on the statement of Ullrich and Reich (*Annal. der Landwirtschaft* 49, 122; a paper which is not accessible to me) that they have found stearic and oleic acids in the wool-fat, and remarks occasionally that oleic acid seems to be present in large quantities. But he hastens to add that he did not isolate the oleic acid from it. The fact that the fatty acids of the neutral fat melt at a low temperature, may have been the cause of this annotation. The iodine absorption of these fatty acids was found by me 17 per cent., and this definitely excludes a larger quantity of oleic and other unsaturated fatty acids.

In conclusion I wish to give the complete analysis of this recovered grease; the figures with which the preceding notes are interspersed, furnish us with the necessary data to base our calculations upon. For the quantitative estimation I proceeded as follows:—About 5 grms. of the recovered grease were dissolved in alcohol and titrated with half-normal aqueous caustic soda until pink to phenolphthalein; thus I found that 1 grm. of the grease required 0.71 cc. 1/1 normal KOH for saturating all the free acids.* Another 5 grms. were boiled with an excess of alcoholic potash and the amount actually used for saturating the free acids and the combined acids determined by titrating back that excess; it was found that 1 grm. of the fat wanted 2.19 cc. 1/1 normal potash. The same test was used for estimating the unsaponifiable matter (*i.e.*, the alcohols), for which I obtained the figure 36.47 per cent. It was now only necessary to determine the volatile fatty acids by the well-known Reichert-Meissl process. One grm. of the fat

* One point, that might be raised, has not been considered at all, viz., the possible presence of anhydrides in the recovered grease. Supposing they were present, the titration for free acids would not show them. They would have passed into the ethereal solution of the neutral fat and unsaponifiable matter, and at last been extracted along with unsaponifiable matter by means of alcohol; for the comparison of the analysis of parts A. and B. shows that B. contains less fatty acids than A. But an error due to such a possibility is completely eliminated by the method adopted sub. II of the complete analysis.

contained a quantity of volatile acids which required 0.124 cc. 1/1 KOH for their neutralisation.

All the figures given are the means of three experiments, agreeing well with each other. The calculation is now easy. The volatile acids may be assumed to have the mean molecular weight 104 (for $C_3H_7O_2$), which gives us $10.4 \times 0.124 = 1.28$ per cent. volatile fatty acids. It is pretty safe to assume that the volatile acids occur in the free state, although Sebülze points to the possibility of the presence of cholesteryl acetate; therefore we calculate for the remaining free acids in one gram.—

$$0.71 - 0.124 = 0.586 \text{ cc. } 1/1 \text{ KOH,}$$

which, for the mean molecular weight 345 (as found above), gives $34.5 \times 0.586 = 20.22$ as the percentage of the remaining free fatty acids. The combined fatty acids required $2.19 - 0.71$ cc. 1.48 cc. = 1/1 KOH, and this leads us for the mean molecular weight 327.5 to—

$$32.75 \times 1.48 = 48.47 \text{ per cent.}$$

as the amount of combined fatty acids, calculated as hydrated acids.

In practical analysis it may not be possible to use such a detailed method as I did, but it is at least necessary to prepare all the fatty acids (both free and combined acids) washed free from the volatile acids and determine their mean molecular weight by titrating with alcoholic potash. I found in this way the mean molecular weight of all the fatty acids (minus the volatile acids) 332 (see above), and this gives, as their saturation required—

$$2.19 - 0.124 = 2.066 \text{ cc. } 1/1 \text{ KOH;}$$

$$33.2 \times 2.066 = 68.59 \text{ per cent.}$$

for all the fatty acids as hydrated acids.

For better comparison I subjoin the analysis calculated by both ways in the tabulated form:—

	I.	II.
	Per Cent.	Per Cent.
Volatile acids.....	1.28	1.28
Insoluble free fatty acids	20.22	68.59
Combined fatty acids*	48.47	
Unsaponifiable matter†	36.47	36.47
	106.44	106.34

* As hydrated acids.

† *i.e.*, alcohols.

The figure 68.59 might be checked by directly weighing all the fatty acids on a weighed filter; but in this case, owing to the formation of inner anhydrides, Hehner's value would be found too low. Still, for a commercial analysis such a method may have some advantages and may be worthy of the notice of analytical chemists.

Considering the difficulty of titrating such dark solutions as were obtained in the course of the analysis and the consequent errors caused by a slightly erroneous determination of the molecular weights, I think, the *sm* may be looked upon as working out in a fairly satisfactory way. Of course, part of the surplus above 100 is due to the elements of water having been added during the saponification.

If we wish to further detail these figures, all of which have been determined directly, we may introduce the percentage of unsaponifiable matter which was found above by calculation as 6.21 per cent. of part B. Part B, forms $(48.47 + 36.47)$ per cent. = 84.94 per cent. of the recovered grease or, rather, as we have to make a deduction for the elements of water added—say 1.94 per cent. = 83 per cent. wherefrom we calculate $83 \times 0.0621 = 5.15$ per cent. for the unsaponifiable matter in the grease. Then the analysis would read thus:—

	Per Cent.
Volatile acids.....	1.28
Insoluble free fatty acids.....	20.22
Combined fatty acids.....	48.47
Combined alcohols.....	31.32
Unsaponifiable.....	5.15
	36.41

The recovered grease contains therefore, in round figures, after deduction of 1.76 per cent. for the elements of water added during saponification, 78 per cent. neutral fat.

I was fortunate enough to obtain the distillates of this very same wool-fat, both the liquid and the solid parts of it, which had been prepared on a large scale in oil-works. The examination of the liquid part was conducted on similar lines as that of the raw fat. First the free acids were neutralised and the neutral fat *plus* unsaponifiable matter extracted by means of ether and recovered from it. It is important to note that no intermediate layer was noticed in this case. The mean molecular weight of the free fatty acids was found to be 286, and therefore they may be looked upon as a mixture of oleic, stearic, and palmitic acids with a small percentage of higher fatty acids.

1 gram. of the oil required 1.92 cc. 1/1 KOH for neutralisation of the free fatty acids; therefore we have $1.92 \times 28.6 = 54.91$ per cent. free fatty acids in the oils. As the complete saponification of the neutral oil took only 2.10 cc. 1/1 KOH it was evident that the amount of neutral oil could be very small only. A method for separating the neutral fat from the unsaponifiable matter could not be found as the latter was also insoluble in alcohol. I had therefore to content myself with preparing and estimating the acids only which were contained in the neutral fat. For this purpose the oil obtained from the ether was saponified by means of alcoholic potash, and the fatty acids recovered from the resulting soap solution; here it was noticed that the intermediate layer mentioned repeatedly above made its appearance. The acids from the neutral fat titrated with aqueous soda gave in one case the molecular weight 558; another preparation from another quantity gave 466. The latter heated to 150° C. gave the molecular weight 763, and this figure remained the same when the acid which had been used for the titration was recovered from its soap and reheated to 160° C. It was clear that the difference of the molecular weights was due to a varying degree of anhydration, and in that case both preparations ought to yield the same molecular weight, when boiled with an excess of alcoholic potash. Such, indeed, was the case, for I found for both acids the molecular weights 393 and 395, which settles definitively 394 as the true value. The percentage of combined fatty acids in the oil is therefore $39.4 \times (2.10 - 1.92) = 7.09$ per cent.

The alcohols combined with these fatty acids would be found in the unsaponifiable matter, which had to be examined next. On complete saponification the distilled fat showed 38.8 per cent. unsaponifiable matter. A preliminary estimate of the quantity of alcohols contained in the unsaponifiable part could be gained by boiling weighed quantities with acetic anhydride and collecting the resulting product on a weighed filter. The following four experiments were carried out:—

Substance employed.	Acetate obtained.	Substance employed.
Grms.	Grms.	Per Cent.
4.9167	4.9483	100.9
5.2735	5.2874	100.2
2.9995	3.0281	100.9
4.3592	4.3979	100.85
	Means	100.71

At the first blush one might feel inclined to ascribe the *plus* of 0.71 per cent. to the errors of the method, but in that case the question had to be answered: What has become of the alcohol with which the combined fatty acids have formed the neutral oil, no glycerol having been found, even if the oil contained no free alcohol? Assuming for a moment that that alcohol was cholesterol, molecular weight 372, then about an equal percentage to that of the combined fatty acids (M.W. 394) must be present in the oil, *i.e.*, 7 per cent.; therefore the unsaponifiable matter, in which these 7 per cent. are dissolved would contain the

alcohol to an extent of 18 per cent., and on boiling with acetic anhydride an increase of $18 \times 0.113 = 2.35$ would take place, or in other words the unsaponifiable matter, as used in the last four analyses, ought to have yielded 102.35 per cent. But, naturally, we have to base such a calculation on the figures found when examining the neutral fat of the recovered grease (see above), namely, 239 as the mean molecular weight of the alcohols, and 12.7 per cent. as their increase on boiling with acetic anhydride; this leads us to 101.3 per cent., with which the 100.71 actually found compare favourably. (An elementary analysis with the view of finding oxygen by difference would not have given unmistakable results.) The same calculation gives 4.26 per cent. alcohols in the distilled grease or 11 per cent. alcohols in the unsaponifiable part; consequently, the by far greatest part of the latter consists of hydrocarbons, a conclusion which is confirmed by its insolubility in acetic anhydride. The alcohol might have been extracted by means of this reagent, but on account of its high cost I had to prefer common alcohol, in which the hydrocarbons, especially at ordinary temperature, are far less soluble than the alcohols. The unsaponifiable matter was therefore repeatedly boiled up with alcohol, and the latter, after a moment's settling, poured off from the undissolved oil. On cooling slightly there separated the greatest part of the dissolved hydrocarbons, and the still warm alcohol gave at ordinary temperature a crop of indistinct crystals, which, on recrystallising from alcohol-ether yielded a semi-crystalline mass, to all appearances similar to the mixtures of alcohols as obtained during the examination of the recovered grease. The alcohols thus prepared show very distinctly the ischolesterol reaction.

Through the exhaustion of the unsaponifiable matter by means of alcohol the hydrocarbons were at last left behind. Their insolubility in acetic anhydride, and to some extent in alcohol, as well as their behaviour towards nitric acid, characterised them as hydrocarbons. A closer examination of them is, for want of proper methods, a hopeless task, and all that could therefore be done with them was to distil them in vacuo. Thus three fractions were obtained. All of them possessed the smell which the crude distillates of paraffin oils, boiling at the same temperature, possess. These fractions are a little more defined in the subjoined table:—

Fraction.	Sp. Gr. at 80° F. compared with Water at 80° F.	Appearance.
1st	0.8513	Clear, bright yellow oil; bloom.
2nd	0.9162	Bright oil, partly solidifying; bloom.
3rd	0.9180	Darker oil, solidified; bloom.

The residue was pitch.

I repeat the complete analysis of the distilled grease in a tabulated form:—

	Per Cent.
Free fatty acids	54.91
Combined fatty acids	7.02
Unsaponifiable	38.80
	100.73

which can be resolved in the following way:—

	Per Cent.
Free fatty acids	54.91
Combined fatty acids	7.02
Combined alcohols	4.26
Hydrocarbons	31.54
	100.73

A more rapid way of analysing such distilled grease, recommendable to analytical chemists, would be to titrate as above, but to use for the determination of the mean molecular weight *all* the fatty acids (free and combined) and *alcoholic* potash or soda. Proceeding in this way I

found the mean molecular weight of all the fatty acids 300.5 (titration with aqueous soda gave 317), and therefore the percentage of all the fatty acids 300.5×2.1 per cent. This way of calculating leads to the equally satisfactory result:—

	Per Cent.
Fatty acids	63.1
Unsaponifiable	38.8

The weighing of all the fatty acids directly—Hehner's method—would in *this* case be nearly as accurate as can be wished for, and the adoption of such a gravimetric method (preferably combined with the direct determination of the Unsaponifiable) would remove the uncertainty adhering to the commercial analysis of such distilled grease, and caused by the *assumption* of a molecular weight for the acids and calculation of the unsaponifiable matter by difference.

The solid part of the distilled grease was only cursorily examined. 1 grm. of it required 2.19 cc. normal caustic soda for saturating the free fatty acids. On boiling the fat with alcoholic potash 1 grm. consumed 2.30 cc. The last figure points to the presence of neutral fat, and its quantity would be found corresponding to the difference $2.30 - 2.19 = 0.11$. The unsaponifiable matter amounted to 34.05 per cent.

A comparison of the analyses of the recovered grease and of the distillates therefrom shows that hydrocarbons have been formed during the distillation to a large extent—a fact which cannot be at all surprising. On examining such distilled oils, the origin of which may not be known, one might easily feel inclined to declare these hydrocarbons as mineral oil. But such a misnomer, besides suggesting fraudulent intentions, might lead to unpleasant consequences for the buyer of such oils, for insurance companies generally become suspicious when “mineral oil” is only mentioned. The distilled grease legitimately contains a larger amount of hydrocarbons, which, as *I am given to understand*, are said to constitute the valuable properties of such oils.

As there is no method known for distinguishing the hydrocarbons formed by destructive distillation from any (fraudulently) added mineral oil, due caution should be exercised in giving a report on such oils.

A comparison of the two analyses further throws an interesting light on the destruction that takes place. We notice at once that the neutral fat constituting as much as 78 per cent. of the recovered grease has been destroyed nearly completely.

In the first instance the ethers will have been broken up into their fatty acids and hydrocarbons, the latter being naturally formed in consequence of the fatty acids claiming all the available oxygen for themselves. We know this from actual experiments. Berthelot has shown that cholesteryl stearate becomes acid on heating. We know further from Smith's experiments (Ann. Chim. Phys. [3] 6, 40) that cetyl palmitate distilled under ordinary pressure splits up into palmitic acid and cetene according to the equation $C_{15}H_{31}CO.O.C_{16}H_{32} = C_{15}H_{31}COOH + C_{16}H_{32}$. Finally Kraft (Ber. 16, 3019) has prepared, by the same reaction, from the palmitates of dodecetyl alcohol, tetradecyl alcohol, cetyl alcohol, and octadecyl alcohol the hydrocarbons: dodecylene, $C_{12}H_{24}$; tetradecylene, $C_{14}H_{28}$; cetene, $C_{16}H_{32}$; and octadecylene, $C_{18}H_{36}$.

As the distillation of the recovered grease is carried out by means of superheated steam, it is not surprising to find that part of the neutral fat escaped destruction, for we know that cetyl palmitate, e.g. can be distilled in vacuo without undergoing decomposition.

The free alcohols—or if any be formed by the destruction taking place in such a direction—will at such high temperatures easily lose water and contribute their share to the production of hydrocarbons.

It is well known that the cholesterol is decomposed into hydrocarbons when subjected to dry distillation; the other alcohols may undergo similar changes, and that not only during distillation, but already in the preceding operation of washing with concentrated sulphuric acid. Cholesterol,

e.g. is converted by this acid into three isomeric hydrocarbons as Zwenger (Liebig's Annalen (1848), 66, 5) has shown.

The fatty acids in their turn undergo a breaking up into acids of lower molecular weight, and, to all appearances, in particular the higher fatty acids will be subject to this change, for oleic, stearic, and palmitic acids can be easily distilled without much destruction in a current of superheated steam. A small quantity of hydrocarbons, however, are always formed when these lower fatty acids are distilled in candle works, and so we have to look to some extent to the fatty acids as a further source of the distilled-grease-hydrocarbons.

The chemical constitution of some of these higher fatty acids, which must be claimed as hydroxylated fatty acids, seems to make them specially fit—I nearly said to predispose them—for this change. A certain amount of proof can be adduced from the above-recorded observations for this supposition. The formation of that difficultly-soluble soap, so unpleasantly noticeable during the neutralisation of the free fatty acids of the recovered grease, was completely absent when the distilled grease underwent the same operation. On saponifying, however, the neutral fat of the latter, that intermediate layer made its appearance again; this cannot be adduced as contradicting my assumption, for it simply shows that the current of steam mechanically carries over the neutral fat, and thus withdraws it from the destructive influence of the high temperature.

III.—QUANTITATIVE ESTIMATION OF CHOLESTEROL.

During the examination of the recovered grease I felt very much the want of a method of estimating cholesterol quantitatively. The separation of cholesterol in substance or in form of its ethers as cholesteryl acetate or benzoate could, of course, not lead to quantitative results. An optical method: the determination of the cholesterol by the rotation of the plane of polarised light, was *a priori* excluded as isocholesterol, which is also present in the wool-fat, is dextro-rotatory, and would by compensation with the laevo-rotatory cholesterol lead to completely erroneous results.

A colorimetric method, based on Liebermann's cholesterol reaction, has been proposed recently by Burchard (Ber. 1890, Ref. 752), but it was, of course, out of the question to use this method for my purposes.

I had therefore to look out for some new method. A contemplation of the formula for cholesterol, $C_{26}H_{42}O$, suggests at once the possible use of methods which are generally practised in the analysis of fats. Cholesterol being an alcohol, it should be easily transformed into an ether; moreover, cholesterol being an unsaturated compound it might add iodine; and the existence of the dibromide, which has been described by Wislicenus and Moldenhauer (Liebig's Annalen, 146, 178), seemed to point to such a method. All that had to be settled by experiment was to determine whether the two reactions took place quantitatively, and for this purpose it was by no means necessary to isolate the resulting derivatives, as the saponification value and the iodine absorption value could give a satisfactory answer to that question. The experiments showed that the cholesteryl acetate and the di-iodide of cholesterol are formed quantitatively, and that these two methods afford an easy means for the quantitative estimation of cholesterol, and consequently also of isocholesterol. I subjoin the details of the analysis:—

Pure cholesterol, prepared from calf brains (in the works of Kahlbaum), was boiled with $1\frac{1}{2}$ its quantity of acetic anhydride in a flask connected with a reflux condenser; the resulting product was washed on the filter with warm water until the wash-waters showed no longer an acid reaction, and the filter with the precipitate brought into a flask to be boiled with an excess of standardised alcoholic potash. The alkali used was determined by titrating back the excess.

I.

1.5681 grm. cholesterol transformed into the acetate required for saponification 8.55 cc. $\frac{1}{2}$ normal KOH; consequently saponific. value 137.4.

II.

1.9860 grm. cholesterol required 10.3 cc. $\frac{1}{2}$ normal KOH saponific. value 132.4.

Theory indicates for the formula $C_{26}H_{42}O.C_2H_3O$ the saponification value 135.5.

For the determination of the iodine absorption value the cholesterol was dissolved in 50 cc. chloroform and 25 cc. of an iodine solution as well as of a mercury bichloride solution—prepared according to Hubl's prescription and kept separately until used—added. The unabsorbed iodine was titrated back with a sodium hyposulphite solution, 17.4 cc. of which corresponded to a quantity of 0.2 grm. iodine. It goes without saying that a blank test was used at the same time.

I.

0.6060 grm. cholesterol absorbed iodine equivalent to 35.9 cc. of the above sodium hyposulphite solution; wherefrom iodine value 68.09.

II.

0.5617 grm. cholesterol took 33.65 cc. of the solution; iodine value 67.3.

Theory requires for the formation of $C_{26}H_{41}OI_2$: 68.3 per cent. The last experiments prove that cholesterol contains one $CH=CH$ group in the lateral chain of one benzene nucleus.

After the above results had been obtained I could try how far cholesterol could be separated from other alcohols. Possessing a pure specimen of cetyl alcohol I prepared from weighed quantities a mixture of cholesterol and cetyl alcohol. The iodine value of the mixture gave the quantity of cholesterol direct. This acetate method could not be employed in a desired way, as the cetyl acetate—melting at about 22° C.—would pass through the filter, and when I cooled the filter by means of ice, filtration could not be brought to an end. I dissolved therefore the acetates in absolute alcohol, from which cholesteryl acetate is well known to crystallise in needles. Thus I obtained a crop of crystals, having a saponification value of 138.4 and 132.6 in two experiments, while the respective yields were 69.03 per cent. and 59.92 per cent. of the cholesteryl acetate which had been formed from the cholesterol weighed in. The mother-liquor from the crystals gave another crop, which in the second experiment yielded another 9 per cent. with the saponification value 168.

The first crop of crystals were nearly pure cholesteryl acetate, whilst the second crystallisation contained already notable quantities of cetyl alcohol (saponification value 197.5). It is evident that cholesteryl acetate cannot be separated completely from cetyl acetate by crystallisation from alcohol.

As I had obtained in the examination of the distilled grease mixtures of alcohols and hydrocarbons I prepared mixtures of pure cholesterol and of a mineral oil 0.880 sp. gr. to test both methods for the estimation of cholesterol in such a case.

0.8220 grm. cholesterol were mixed with 0.2393 grm. of the mineral oil (which had been tested before with acetate anhydride and found—as expected—not to require any KOH) and boiled with acetic anhydride. The mixture required for saponification 4.44 cc. half-normal KOH. The 0.8220 grm. cholesterol must have given theoretically 0.9148 grm. acetate, which had consequently the saponification value 136.1 instead of 135.5.

The percentage of cholesterol in the mixture could have been found at once by means of the formula—

$$P = \frac{a \times 561 + 372}{S \times 414 + 135.5 \times 100}$$

where a is the number of cc. 1/1 normal potash used, S the substance weighed, 56.1 the molecular weight of KOH, 372 that of cholesterol, and 414 of cholesteryl acetate, whilst 135.5 is the saponification value of cholesterol. The calculation gives 77.82 per cent. cholesterol; the mixture actually contained 77.45 per cent.

The iodine method gave for the mixture of cholesterol and mineral oil equally good results. The mineral oil absorbed 26.3 per cent. iodine when tested separately.

(1.) A mixture of 0.7208 gm. cholesterol and 0.3379 gm. of this mineral oil absorbed 54.38 per cent. iodine, that is for the sum $0.7208 + 0.3379$ a quantity of 0.5757 gm. iodine. The theoretical calculation gives—

$$\frac{0.7208 \times 68.3 + 0.3379 \times 26.3}{100} = 0.5810 \text{ gm.}$$

(2.) 0.7263 gm. cholesterol + 0.3361 gm. mineral oil absorbed 54.3 per cent. or 0.5771 gm. iodine; theory requires 0.5845 gm.

This second method will allow a limited application only, as the iodine value of the hydrocarbons must be known, which will not be always the case.

In conclusion I wish to say a few words about the qualitative reactions for cholesterol and ischolesterol. Colour reactions, especially those requiring the use of concentrated sulphuric acid, should always be looked upon with some suspicion, which can only be heightened if we remember the fate of, e.g. the isatine reaction for benzene, of Laubenheimer's reaction for phenanthrenequinone, &c. Liebermann's "Cholesterol" reaction for cholesterol—acetic anhydride and sulphuric acid; sharper still is the test in the modified form proposed by Burchard, 2 cc. chloroform, 20 drops of acetic anhydride and sulphuric acid—is a beautiful reaction for pure cholesterol, but unfortunately resins possess a reaction so similar to the cholesterol reaction that a discrimination would be difficult. The corresponding reaction for ischolesterol, recently proposed by Schulze (Ber. 24, Ref. 671), (green fluorescence) is very sharp too, but in a mixture of ischolesterol and cholesterol, which which we undoubtedly have in the alcohols prepared from "Lanolin," the ischolesterol reaction prevails, as I had occasion to observe. Amongst a large number of experiments I only occasionally succeeded in noticing the pink colouration due to the presence of cholesterol, and it would therefore be rash to pronounce absence of cholesterol, if the green fluorescence only is noticed. The reaction with iron perchloride and strong hydrochloric acid on a porcelain crucible cover is not exclusively peculiar to cholesterol, for turpentine, camphor a.o. behave in the same way (Weyl, Ber. 1886, Ref. 619).

DISCUSSION.

The CHAIRMAN remarked that the subject was one of great interest to members, as some 12,000 tons of wool grease were recovered annually from mills in the district alone. The author had shown that the analysis was complicated in the case of pure wool grease; this was much more the case when grease was adulterated with mineral and rosin oils. Samples of greases, though similar in appearance and containing equal amounts of saponifiable matter, might vary in value from 8*l.* to 16*l.* per ton. He exhibited samples and illustrated the methods of determining commercial value in the case of a grease worth 13*l.*, which showed:—

1. Specific gravity.....	0.941
2. Flash point	415° F.
This shows it can contain no mineral oil after it has been established that no rosin oil is present.	
3. Setting point of fatty acids	101° F.
4. By titration of saponifiable matter and calculation to a molecular weight of 282 there was found:—	
Saponifiable	= 51.21 per cent.
Unsaponifiable (by difference).....	= 46.79 "
" (by ether extraction) = 41.70 "	

The difference between the calculated and observed amount of unsaponifiable matter gave, roughly, an indication of cholesterolinoid bodies present. He calculated for every 1 per cent. of difference 10 per cent. of cholesterolin present. The cerotic compounds left unsaponified formed a hard mass of high specific gravity. On distillation the cholesterolinoid bodies changed into other hydrocarbons, and the specific gravity sank (in this sample) to 0.914 and the flash point to 330° F. The proportion of fatty acid did not alter more than 2 per cent. These hydrocarbons had the appearance of mineral oils. Dr. Hess concluded by

expressing a wish that chemists would adopt some uniform method of determining the amounts of saponifiable and unsaponifiable constituents in such greases, since results of analyses of the same material by different chemists sometimes differed as much as 5 per cent.

Mr. FAIRLEY asked whether dry distillation, or distillation with superheated steam, was employed for purifying the grease?

The CHAIRMAN said that superheated steam was always used.

Mr. FAIRLEY thought it surprising that so much hydrocarbon should be formed in presence of an excess of steam.

The CHAIRMAN replied that the hydrocarbons were present before, but in a different form.

Mr. RICHARDSON asked Dr. Lewkowitsch if he considered the "acetyl values" were reliable, the process being used as supplementary to the ordinary methods in the general analysis of oils in soap, &c. He mentioned the action of oils on samples of tops; after an interval of a month the iodine absorption value was reduced from 100 to 50, due apparently to oxidation of the oil.

Professor HUMMEL was surprised to learn that there was so much unsaponifiable matter in distilled grease used to oil wool for spinning. He believed such bodies were difficult to scour; the difficulty had been attributed to intentional adulteration with mineral oil. He desired to know what sort of a residue was left on distillation, and whether anything was known of its composition. He had some years ago obtained a similar waxy product from apple parings by extraction with ether, and it had recently been shown that cholesterolin exists in vegetable material.

The CHAIRMAN said mineral oil was often mixed with grease and was undoubtedly deleterious to the wool. He thought Dr. Lewkowitsch wished to find some method of distinguishing this from cholesterolinoid material. In reply to Professor Hummel he stated that the residue left on distilling grease was pitch. The distilled grease from the sample shown was pressed into stearine and oleine, and the former contained 33 per cent. of unsaponifiable matter, and had a melting point of 118° F.

Mr. PROCTER inquired if Dr. Lewkowitsch had ever come across an animal oil possessing a distinct bloom like mineral oils. He had once obtained, by pressing fats obtained in gelatin manufacture, an amber-coloured oil with green fluorescence.

The CHAIRMAN replied that the hydrocarbons obtained by the distillation of cholesterolin had a distinct bloom, palm oleine occasionally, showed this fluorescence.

Mr. MACKAY asked how it was that an increase of 10 per cent. in the unsaponifiable matter caused a rise in value of 3*l.* per ton, and, if so, would not the pure cholesterolin products be very valuable.

The CHAIRMAN said the increased value was due to the extended application of such greases, as, for instance, in the manufacture of lanolin and vinolia soap. If it were possible to obtain cholesterolinoid substances cheaply and free from fatty acids they would be most valuable for lubricating purposes.

Mr. MANSBRIDGE said he had examined large numbers of greases and had never found more than 1½ per cent. of neutral oils; he believes that neutral fats to be almost entirely decomposed in the still.

Professor HUMMEL stated that attempts had been made of recent years to scour wool with petroleum ether, carbon disulphide, &c., thus extracting a fatty matter containing cholesterolin. He wished to know whether a large sale of the extracted matter could be assured, supposing such a process were introduced.

The CHAIRMAN replied that such processes had often been tried, but without success; under the influence of hot solvents, the wool became brittle and yellow. The products would be very valuable, but the wool would be spoilt.

Dr. LEWKOWITSCH severely criticised Dr. Hess' analyses (the details of one of which are given above). The 51 per cent. "saponifiable" would only be free fatty acid. The 46.79 per cent. "unsaponifiable" be considered not at all reliable; it was determined merely by difference, but he should like to know how and whether that was so, since 51.21 and 46.79 gave 98 per cent. only. "Saponifiable" was also determined by calculating from an assumed molecular weight. The extraction with ether could not give too low a value; it might give a value *higher* than the true one, as a small amount of soap might have been extracted and overlooked. He therefore attached no scientific value to these figures.

The CHAIRMAN defended his analyses and remarked that they agreed within 0.1 per cent. with analyses by Allen and other chemists of the same samples. When cholesterinoid bodies were present it was usual to assume a molecular weight not of 282 but over 300 in calculating the results. In the results above given, 41.7 per cent. would be taken as correct. He knew the other figure was incorrect, but the difference between it and the experimental figure gave a rough idea of the amount of cholesterin present.

Dr. LEWKOWITSCH, answering Mr. Mansbridge, said that his paper only dealt with this one fat, and that if Mr. Mansbridge questioned the amount of combined fatty acids in the distilled grease, he could only refer to his figures. He had found the mean molecular weight of the free fatty acids of the distilled grease = 286; the molecular weight of all fatty acids (combined and free) = 300.5 and the molecular weight of the combined acids 394. The amount of combined fatty acids corresponds to the difference of KOH used for neutralising and saponifying = $2.10 - 1.92 = 0.18$ and $0.18 \times 39.2 = 7.02$ as to the hydrocarbons. He showed three fractions obtained by the distillation of the crude hydrocarbons contained in distilled wool-grease, the specific gravity of which was respectively 0.851, 0.918, 0.92. Admixture of resin oils would, he remarked, be shown by the high specific gravity of these distillates. The polariscope could not be used as the hydrocarbons obtained from cholesterins are optically active, and would contain cholesterin as shown. In answer to Mr. Fairley, he said that superheated steam does not act as so much water would do, but simply as a vehicle to convey the products out of the still as quickly as possible. Replying to Mr. Richardson, Dr. Lewkowitsch suggested that the oil used on "tops" may have been adulterated with linseed oil, which, as is well known, contains a series of acids from $C_{18}H_{36}O_2$ to $C_{18}H_{30}O_2$, the least saturated of which ($C_{18}H_{32}O_2 = C_{18}H_{20}O_2$) easily take up O.

Mr. RICHARDSON explained that he had been unable to find any linoleic acid in the oil.

Dr. LEWKOWITSCH, speaking of the "acetyl values," remarked that acetic anhydride, as he had shown recently, acted on normal fatty acids, forming anhydrides, e.g. $(C_{15}H_{31}CO)_2O$ which is not attacked easily by aqueous caustic soda, and not hydrolysed completely by it; on the other hand, acids of a constitution similar to—

take up one (C_2H_3O) group, and the saponification value comes out twice as great as that of the original acid.

With regard to *bloom*, he had not noticed it on animal oils, but it was shown by the hydrocarbons under discussion.

He further stated that the substances obtained from recovered grease should not be used in the manufacture of household soaps, but are said to do for milling soaps.

The *pitch* left behind in the retort is valuable for greasing the necks of hot rollers.

Obituary.

THOMAS W. B. MUMFORD.

It is with regret that we have to announce the death of Mr. Thomas W. B. Mumford, Honorary Secretary of the London Section of the Society.

Early in life he entered the employment of Messrs. James Gibbs and Co., vitriol and manure manufacturers, in a comparatively humble position, and by his skill, energy, and perseverance, rapidly rose in the estimation of the firm, and was appointed manager of their Plymouth works, and at a later date held the same position at their principal works in London. He joined the Society of Chemical Industry in 1883, and succeeded Mr. Tyrer as secretary of the London Section in 1890, on the elevation of the latter to the Chair. He was the author of various improvements in his own branch of manufacture, particularly in the construction of roller-mills for phosphates, and was joint inventor with his colleague, Mr. Moodie, of the now well-known Separator. He discharged his secretarial duties in an admirable manner, and was universally esteemed by all who knew him, not only for his high intellectual and moral qualities, but also for his kindness of heart and readiness to serve others, which endeared him to all and rendered his early death so much to be deplored. He was taken ill at the Annual General Meeting in Dublin in July last year, and soon afterwards symptoms of consumption declared themselves. A visit to Bournemouth failed to effect any improvement, and upon his return he took to his bed.

He died on 26th December 1891, in the 47th year of his age, leaving a wife and two children to mourn his loss.

CHARLES HEISCH.

MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.
THE CITY GAS EXAMINER; ALSO PAST PRESIDENT OF
THE SOCIETY OF PUBLIC ANALYSTS.

CHARLES HEISCH was born at Blackheath, Kent, on the 2nd August 1820, and was the youngest son of the late Frederick Heisch, of Messrs. Cox, Heisch, and Co., America Square, London. Even in boyhood he was distinguished by his partiality for chemical studies, and was clever in constructing scientific apparatus and models. This led to his being placed with Mr. Richard Phillips, who was then occupying temporary premises at Craig's Court, Charing Cross, during the construction of his laboratory and lecture room in the Museum of Economic Geology, Jermyn Street. In 1842, Heisch became assistant to Dr. Leeson at St. Thomas's Hospital, and whilst here made chemical analyses of the large number of calculi forming the collection in the Anatomical Museum. Six years later, in 1848, he was elected joint Lecturer on Chemistry with Mr. Thomas Taylor at the Middlesex Hospital, a post which he retained for upwards of 20 years. Meanwhile, in 1868, he was appointed Superintending Gas Examiner to the Corporation of London, the duties of which office he continued to fulfil almost up to the time of his death on the 2nd January last.

Mr. Heisch attended the Jubilee Meeting of the Chemical Society in May last, and was publicly referred to as being one of the three or four survivors who took part in the original formation of that Society in March 1841. He was, besides, one of the founders of the Society of Public Analysts, and for some years Secretary, becoming President, as stated, in 1881-82. He likewise took an active part in the formation of the Photographic Society, and has been for many years a member of this Society. His most important contribution to chemical science was the "Sugar Test" for determining the quality of potable waters (*Chem. Soc. Jour.* 1870, Vol. XXIII., 371.) This, with other papers in the *Journal of Gas Lighting*, the *Analyst*, and *Chemical News*, besides sundry researches in photographic practice, such as the accurate rendering of coloured objects by means of bromized collodion, and improvements in apparatus, make up the sum of Mr. Heisch's experimental record. He married somewhat late in life, and leaves a widow, besides many private friends, to mourn his loss.

WILLIAM DITTMAR, LL.D., F.R.S.

FORMERLY VICE-CHAIRMAN OF THE GLASGOW AND
SCOTTISH SECTION OF THE SOCIETY
OF CHEMICAL INDUSTRY.

PROFESSOR OF CHEMISTRY IN THE GLASGOW AND
WEST OF SCOTLAND TECHNICAL COLLEGE.

It is with deep regret that we have to announce the death of Professor Dittmar, of the Glasgow and West of Scotland Technical College. Although for the past few weeks he had not been quite well, no symptoms of a serious kind presented themselves so as to interfere with the discharge of his duties or to cause anxiety to his friends. On Tuesday forenoon he delivered his lecture as usual, although a want of readiness was noticeable. In the earlier part of the afternoon he returned home, and, while evidently out of sorts, it was only after four o'clock that it seemed needful to ask medical advice. He passed away shortly before midnight. It is satisfactory to know that he was spared pain, and complained merely of a feeling of uneasiness. The immediate cause of death was a failure of the nerve centre regulating the breathing, and there was a slight cerebral hemorrhage.

Since the year 1874, when he was appointed, on Professor Thorpe's resignation, to the Chair of Chemistry in the Anderson's College, the striking personality and the high repute of Dr. Dittmar have been well known to the Glasgow public. He was called to occupy a chair deriving its prestige from the names and work of Graham, Ure, and Penny, and the success with which Professor Dittmar discharged his academic duties, while extending the domain of his science, proves that his presence and work shed an additional lustre on the chair and college, already illustrious through these names. During his 17 years of work here, Professor Dittmar has made his laboratory second to none perhaps in Great Britain as a training school of young men devoted to chemistry as a profession. From comparatively small numbers in the earlier years, the laboratory roll has risen to on an average over 50. The reason was not far to seek. Professor Dittmar was a man of admittedly profound knowledge, standing in the front rank of chemists both as a theorist and a practical analyst, an enthusiast gifted, strange as that may seem to be, with an indomitable scientific pertinacity and a far-reaching speculative power, brought into harmony and rendered practically effective by a clear conception of the value of routine. Above all, he had the mark of every great teacher—the power of drawing to himself the hearts of his students, and of controlling and stimulating in them the aspirations which his instruction engendered.

Professor William Dittmar, LL.D., F.R.S., L. and E., was born at Umstadt, near Darmstadt, Germany, in the year 1833, and adds one more name to the list of distinguished chemists, embracing Liebig, Strecker, Kekule, and Schorlemmer, who have made the latter town famous. Intending at first to follow the pharmaceutical profession, he fortunately changed his mind, and entered in 1857 the laboratory of the celebrated Bunsen, who, discerning the promise of his student, offered to Dittmar an assistantship. In this capacity it was that Professor Sir Henry Roscoe made his acquaintance, and he, too, impressed by Dittmar's rare powers, invited him to become his private assistant. After Roscoe's appointment to the Chair of Chemistry in Owens College, Mr. Dittmar accompanied him thither, and only left Manchester to become in 1861 Dr. Lyon Playfair's chief laboratory assistant. In 1869 he returned to Germany, and during the next three years acted as a "Privat Dozent" and lecturer on meteorology at Poppelsdorff. Though offered a chair in Cassel he preferred to return to Scotland in 1872 to hold under Professor Crum Brown the same post that he had held under Sir Lyon Playfair. It is pleasing to think that this led to a deep and lifelong friendship based upon the excellence of heart, frank and genial bearing, and high-souled integrity of both him who is left and him who is gone. It is hard to tell which entertained the higher opinion of the other's nature and scientific power. One thing is certain that Professor Dittmar was habitually called in to co-operate by authorities such as Crum Brown and Dewar as a fellow-expert whose opinion was, to men of science at least, *absolute*. On being offered the newly-instituted Chair of Practical Chemistry in Owens College, he removed to Manchester, only to return after a brief period to Scotland. The trustees of the Anderson's College here did honour to their own judgment and a lasting benefit to chemical science in Scotland in recognising the claims of William Dittmar to a chair such as they had to offer. To the transcendent ability of Professor Dittmar the governors who elected him and their successors have never been blind. So perfectly, indeed, has he performed his functions, and furthered the interests of his college, that, though his ideal of his sphere was by many felt to be almost impracticably high, there must be in all the conviction that it will be very difficult soon to make good his loss.

The labours of Professor Dittmar are, in their abstruseness, thoroughness, and extent, incapable of being either duly detailed here or adequately valued by anyone not himself an expert in physics and chemistry. As a

lecturer we knew him and admired his natural, spontaneous, clear way of conveying his ideas. As a laboratory teacher it was impossible not to be impressed by the light value in which he held labour so long as truth and accuracy might be attained, nor to be almost taken aback by his enormous fertility of resource. Even as a practical analyst commercial men knew his worth. But his work as a scientist must be left to time to estimate. One thing is certain, critics are united in recognising the thoroughness, great variety, and true scientific worth of all he has done. It is not too much to say that the honours which have fallen to him of late years, and the crowning honour of the Graham medal, conferred on him for his laborious, difficult, and successful investigation of the "Gravimetric composition of water," are only first hints of the recognition of his great scientific services. It is only necessary to mention here two of his more generally known original contributions, and which, like the whole of his extensive scientific work, show that striking originality and character that were peculiarly his own. The contribution which is probably best known to the ordinary non-scientific world comprised the incessant and painstaking work of three years, namely, that in connection with the "Challenger" expedition of 1873-76. His work and publications on the chemical balance are known to every scientist, and he was universally recognised as one of the highest authorities on this as on many other subjects. He also wrote numerous and voluminous articles in all the best known cyclopædias of Britain and the Continent, and was a constant contributor to some of the most famous Continental scientific periodicals.

As a man, it is impossible to speak too highly of Professor Dittmar. Widely cultivated, simple in his tastes, unaffected in his manners, genial even to jocularity, he was one who readily endeared himself to all with whom he came in contact. But he was also a man of thorough uprightness, who persisted without flinching in what he thought was right, and who, generous in his antagonism, might find opponents but could leave no enemies. By his family, his students, and his many friends his loss is deeply felt, for it was impossible to find one more domestic in his affections, one more able and willing to advise and aid, or one in whom the light of friendship shone with greater steadiness and purity.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

A New Syphon F. Konther. Chem. Zeit. 1891, 15, 1126.

See under XXIII., page 181.

PATENTS.

A Crusher and Pulveriser. W. C. Morison, Plymouth. Eng. Pat. 14,945, September 22, 1890. 8d.

The apparatus consists of an upright stationary vessel having a hemispherically-shaped bottom, with sides inclining outwards, and having a circular hole in the bottom corresponding with a circular hole formed in the central portion of a hemispherically-shaped cast-iron "piece," upon which it fits and works. The sides of this "solid piece," are also inclined outwards. The material to be operated upon is broken between the "solid piece" and the sides of the vessel, and when crushed sufficiently small, drops into the gradually diminishing space between the sides of the "solid piece" and the vessel, until it reaches the lower end, where it is subjected to a further grinding action, and is finally discharged through the hole in the bottom. The incline of the solid piece can be regulated at pleasure. This piece is prevented from rising during the crushing of the material by the upper portion of the revolving shaft working against discs placed in a rigid frame, thus resisting the upward pressure. The "solid piece" is covered and the sides of the vessel are suitably lined with hard metal.—E. S.

Improved Filter for Oils, Lubricants, and other Fluids. W. H. Wilcox, London. Eng. Pat. 101, January 2, 1891. 6d.

Improvements in Multiple Effect Evaporating Apparatus. A. Chapman, Liverpool. Eng. Pat. 1194, January 22, 1891. 8d.

THE object of this invention is an improvement of "Yaryan" triple effect apparatus. Owing mostly to the employment of long tubular worms, the pipes get readily furled and filled with deposit when treating certain liquors, unless they are blown out and cleaned once or twice a day. This reduces the quantity of work done as well as the density of the concentrated liquor, and the difficulty is sought to be overcome by the addition of a vertical tubular evaporating vessel as shown in the arrangement illustrated.

a b c represent three vessels of a triple effect apparatus; *d* is the additional vessel containing vertical tubes passing through a steam drum; *e* vapour pipe from the last vessel *c* of the "Yaryan" apparatus leading to the steam space of drum *d*. The inverted syphon *f* removes the condensed

There are two claims.—B.

Improved Oil Filter. C. E. Masterman and "Woodhouse and Rawson United Limited," London. Eng. Pat. 1766, February 3, 1891. 8d.

See under XII., page 169.

An Improved Evaporator and Surface Condenser for Producing Pure Distilled Water. W. P. Cotton, London, and E. L. Garrett, Wallington. Eng. Pat. 2141, February 5, 1891. 8d.

In this apparatus the water is evaporated by means of steam and is afterwards condensed. Within a vertical chamber two series of tubes are arranged surrounded by cold water admitted at the lower part of the chamber. Steam admitted to the upper series of tubes heats the water surrounding them, and the steam formed rises to the upper part of the chamber, and passing down pipes to the lower series of tubes is condensed by the cold water surrounding them, flowing away through a pipe to any suitable receptacle.

—E. S.

An Improved Apparatus for Distilling Water and other Liquids. W. T. Cotton, London, and E. L. Garrett, Wallington. Eng. Pat. 2142, February 5, 1891. 6d.

This invention is a modification of Eng. Pat. 2141 of 1891 (see preceding abstract). Two suitably shaped vessels are each divided into two chambers by plates, from which are suspended, in the chamber below, a number of tubes, open at the top but closed at the bottom. Between the two vessels is a cistern supplying water. A pipe from the bottom of the cistern conveys the water to the upper chamber of one vessel, and to the tubes beneath, and overflows through a pipe in the lower part of the upper chamber into the upper chamber and tubes of the second vessel. Beneath these latter tubes an atmospheric gas burner is

placed; this heats the water and the steam rises into the upper chamber and passes by a pipe to the space beneath the tubes in the first-named vessel, and being condensed falls into the space beneath them, whence the distilled water is conducted to any suitable receptacle.—E. S.

Improvements in Couplings for Glass Tubes or for Tubes Lined with Glass. D. Rylands, Stairfoot, and R. Morant, Barnsley. Eng. Pat. 3172, February 21, 1891. 6d.

See under VIII., page 162.

Improvements in or Connected with Vacuum Distillatory Apparatus. E. Luck, London. Eng. Pat. 3955, March 5, 1891. 6d.

THE patentee's aim is to withdraw the spent or exhausted liquor from an ordinary vacuum still without destroying the vacuum, thereby enabling the process to be carried on continuously. For this purpose he connects to the lower part of the still when required, either a pump, or a descending tube of such length as to enable the liquor therein to balance the atmospheric pressure.

The claim is illustrated by one drawing.—B.

Improvements in Machinery or Apparatus for Producing Cold by the Employment of Carbonic Anhydride. E. Hesketh and A. Mareet, London. Eng. Pat. 12,469, July 22, 1891. 8d.

THE patentees claim:—(1.) An arrangement of compound engine with cylinders fixed tandem fashion, and two compressing cylinders attached capable of being thrown out of gear separately, and the whole power of the engine applied to one of the compressors. (2.) An arrangement of condensing pipes in the foundation plate. (3.) and (4.) Passing the cold carbonic acid gas through passages cast on the compression cylinders for keeping them cool.

For details the specification and three sheets of drawings should be consulted.—B.

Improvements in Machinery or Apparatus for Producing Cold by the Employment of Carbonic Anhydride. E. Hesketh and A. Mareet, London. Eng. Pat. 12,676, July 23, 1891. 11d.

To avoid dangerous over-pressure in the passage between the compressor and condenser of such apparatus, when the screw-down valve has been inadvertently closed, the patentees introduce a thin plate of copper or other material calculated to burst when a certain pressure has been exceeded, and they further add a safety valve in some cases outside the relief plate, for the purpose of preventing the escape of the whole of the gas after the plate has burst. The patent also covers a provision for separating any lubricant from the carbonic anhydride after leaving the compressor, and arrangements for facilitating the cleaning of the exterior of the refrigerator pipes by constructing the outer tank in parts for easy removal. When used for the production of ice the pipes are placed close together so as to touch, with a view to separate the ice coating into two parts as it is being formed on the circumference of the pipes, thereby enabling its easy disconnection.

Cross partitions or walls of wood may be fitted to the pipes for further subdivision of the blocks.

There are seven claims and three sheets of drawings.—B.

Improvements in Apparatus for the Automatic Control of Sulphuric Acid Supply to Carbonic Acid Generators used in Aired Water Manufacture and other Industries. H. C. Cox, Olton. Eng. Pat. 17,034, October 7, 1891. 6d.

See under VII., page 162.

Improvements in or relating to Centrifugal Separators for Granular Substances. H. Pape and W. Henneberg, Hamburg, Germany. Eng. Pat. 19,694, November 13, 1891. 6d.

THE object of this invention is to arrange the shaft or spindle carrying the distributing disc, in a continuous working centrifugal separator, in such a manner that all the bearings requiring lubrication are situated above the disc and cover of the machine, whilst also securing a central receiving cavity under the distributing disc. To effect this, the spindle carrying the disc, and the framework are supported on the cover of the receiving chamber. The materials are brought to the disc through a pipe from a suitable hopper, and are prevented from touching the spindle by a sleeve extending centrally within the pipe, and surrounding the central spindle, and are distributed into a series of concentric receivers, the heavier materials being thrown on to the outer receivers, and the lighter particles on to the inner receivers, the lightest of all falling into a central cavity below the disc, whence they may be continuously removed.—E. S.

An Improved Tool for Cutting Glass Tubes. A. W. Chesterton, Boston, U.S.A. Eng. Pat. 20,211, November 20, 1891. 6d.

See under VIII., page 163.

II.—FUEL, GAS, AND LIGHT.

PATENTS.

An Improved Manufacture of Incandescent Bodies for Incandescent Gas Lamps. L. Haitinger, Klosterneuburg, Austria. Eng. Pat. 586, January 12, 1891. 6d.

A SUITABLE refractory material for incandescent gas lights is made by mixing alumina with a small proportion of chromium oxide, and heating the mixture for some time at a high degree of incandescence. The chromium oxide may be partly or wholly replaced by manganese oxide, and either magnesia or zirconium oxide or lime may be substituted for part or all the alumina. Salts may be employed instead of oxides. Fixed acids or alkalis in small quantities are not prejudicial.—D. A. L.

A New Fuel. A. L. Keller, London. Eng. Pat. 1237, January, 23, 1891. 4d.

NATURAL or compressed peat, which may be mixed with sawdust or coal-dust, is taken and moulded into bricks or left in its natural form. Any other suitable absorbing material may be used.

The material after drying is immersed in a suitable bath of hydrocarbons heated to 120° to 150° C. The refuse of petroleum or of shale oils or gas-tar may be used alone or combined with resins, naphthalene, or other cheap solid hydrocarbons.

About 70 per cent. of the original weight of the weighed peat can be absorbed. After drying it is ready for use as fuel.—D. A. S.

Improvements in or connected with the Manufacture of Illuminating and Heating Gases. J. H. R. Dinsmore, Liverpool. Eng. Pat. 2948, February 18, 1891. 8d.

A HYDROCARBON liquid, such as tar, and ordinary coal-gas or water-gas, are passed into an ordinary gas retort heated in the usual manner; in this way a gas of high illuminating power is produced in large quantities. The mixed vapours and gases immediately pass downwards through a vertical pipe which dips under water, and which is kept cool by a water-jacket; the object of this arrangement is to prevent the choking of the retort outlet and to condense the unfixed tarry vapours and arrest any solid particles, so that the other pipes will not get stopped up.

The tar or other liquid may be simply dropped on to the floor of the retort through a sealed pipe, or forced in by the usual devices.—F. S. K.

Improvements in the Manufacture and Storage of Illuminating and Heating Gas. H. Fourness, Manchester. Eng. Pat. 15,469, September 12, 1891. 8d.

THIS invention consists chiefly in passing water-gas combined with that from heavy oil through an additional retort or fixing chamber, which is heated by the producer-gas formed in heating up the producer; in this chamber the gas is further enriched by the vaporisation of light oil which is admitted into the chamber. The inventor claims that by means of this fixing chamber, the gas, besides being enriched, is rendered more stable and so may be carried distances or stored for considerable periods without condensation taking place. Further, that in the formation of the water-gas, when the coke is getting cool, in order to prevent the formation of explosive mixtures on the admission of air to reheat the producer, the supply of oil is shut off and steam blown through for some time, thus clearing the retorts somewhat as well as removing explosive gases. The inventor also claims the mixing of water-gas and oil-gas in a gas-holder provided with an index, by which the proportions of the gases may be ascertained and regulated.—J. C. C.

Improved Arrangement of Coke Ovens and Retorts for the Manufacture of Coke and Illuminating Gas. W. Creswick, Wakefield. Eng. Pat. 17,222, October 9, 1891. 11d.

See under III., page 152.

Improvements in Apparatus for Manufacturing Gas. A. Kitson, Philadelphia, U.S.A. Eng. Pat. 17,557, October 14, 1891. 8d.

THIS invention consists of a somewhat complicated furnace for producing fuel gas for domestic heating, &c. Steam and air are passed downwards through the heated fuel, and the gases are conducted away through the perforated hearth and ash-pit. The furnace is slightly conical to allow the contents to fall easily; the hearth, which has a ring of vertical bars, is perforated, and has both a rotary and up-and-down motion on a hollow shaft which serves as the gas pipe. Near the bottom of this is the horizontal take-off pipe, the lower part of the hollow shaft serves as the ash-pit, and this communicates with a second chamber sealed with water, into which the ash is dumped without escape of gas. By means of the moveable hearth the fuel is stirred, caking prevented, and ash removed. Around the furnace body there are two sets of coils, in the lower of which steam is generated and passes into a chamber, where if necessary it can be charged with oil; then it is superheated in the second coil and is injected with air into the top of the furnace, the air being also heated by having circulated round an annular space round the furnace.—J. C. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Distillation of Coal. P. Mahler. Compt. Rend. 1891, 113, 862—864.

The products of distillation of the Commentry coal were collected and weighed, and their calorific power determined by means of an apparatus of Berthelot. It was found that the calorific power of the products was 96.5 per cent. that of the coal put into the retort. A real loss of calorific power, but a relatively small one, accompanies the process of the destructive distillation of coal.—V. C.

Petroleum and Asphalt at Palena, in Payta. Analogy between Salt and Coal Deposits. C. Ochsenius. Chem. Zeit. 1891, 15, 1866—1867.

The occurrence of petroleum on the coast of Peru between Payta and Tumbes has been known for a considerable time. The exploration has been largely in the hands of an English company, and about one-fourth of the territory for which a concession was granted has been found productive. The oil does not flow with sufficient force to rise spontaneously from the wells, and has to be pumped out. In the valley of Tucigal about 4.7 kilometres from the coast, there are 28 wells varying in depth from 45 to 240 metres, the total daily output of which varies from 1,000 to 2,000 barrels. The crude oil from Zorritos has, according to J. Salathe, a specific gravity of 0.868, and an ultimate composition of 84.9 per cent. of carbon, 13.7 per cent. of hydrogen, and 1.4 of oxygen. The sample gave the following results on distillation:—

° C.	Per Cent.	
20—30	2.8	Rhizoline.
30—80	9.0	Gasoline, of very pleasant aromatic odour.
80—150	11.1	Benzoline.
150—230	18.5	Light kerosene.
230—280	10.0	Heavy kerosene.
	12.8	Light lubricating oil.
Above 280	4.8	Heavy lubricating oil. Free from paraffin wax; becomes buttery at -30°.
	31.0	Pitchy residue.

The petroleum is brought by a pipe-line to the newly made harbour of Palena, which is about 11 kilometres from the wells.

Petroleum also occurs in Peru at Cerro de Paseo and Puno; asphalt is also found in the neighbourhood of the petroleum deposit.

The author draws an analogy between the method by which coal measures have been formed and those resulting in the production of salt deposits. In each case a bar has formed enclosing a bay which serves as a trap for any material that may be deposited therein. Thus, in the case of the salt deposits, a portion of sea-water may be supposed to have obtained access to the bay, and there under the influence of a dry atmosphere evaporated, leaving its saline constituents. In the case of the coal deposits, suspended matter swept down by a river may be conceived as being caught in the bay and gradually consolidated under climatic conditions the converse of those necessary for the formation of a salt deposit into fossil fuel. Many points of resemblance or of diametrical difference between the two processes are indicated in the author's argument.—B. B.

The Origin of Petroleum. A. Veith and C. Schestopal. Dingl. Polyt. J. 1891, 282, 136—138.

THE authors consider that Engler's researches (this Journal, 1889, 607) go far to prove the animal origin of petroleum, the slow decomposition of the bodies of marine animals under the influence of warmth and pressure being capable, under suitable conditions, of its production. The precise mechanism of this change is, however, not yet clear. Zalozecki and Ochsenius have put forward hypotheses (this Journal, 1891, 753; see also preceding abstract), neither of which can be accepted without reservation. The contention of the former that the natural production of petroleum cannot have been effected in the manner indicated by Engler on account of the high temperature (400° C.) used in the researches of the latter, and of the fact that naphthenes are present in petroleum but not in the artificial product, is refuted on the ground that Zalozecki himself postulates a fairly high temperature, and this, in the opinion of the authors, might be produced by the decomposition of animal matter, and that naphthenes were actually present in Engler's product, although confessedly in small quantity. Further, the argument deduced from the alleged absence of nitrogen in petroleum is demolished by the figures of actual analyses, which show that an appreciable quantity is present. Beilby has proved (this Journal, 1891, 120) that almost all samples of petroleum, of whatever origin, contain nitrogen, either in the form of organic bases or ammonium salts. He found that the quantity in petroleum residues, which contain more than the distilled oil, varied from 0.05 per cent. in Baku oil to 3.2 per cent. in the coke from a Scotch raw oil. Nitrogen is also found in the gases accompanying petroleum, 4.31 per cent. being found in an American sample, and 0.94 per cent. and 7.32 per cent. in two samples from Baku. The fact that water is commonly found accompanying petroleum does not necessarily substantiate Zalozecki's idea that it must have played an important part in the production of the latter, as its presence may be due to extraneous sources tapped by the penetration of water-bearing strata, or to the decomposition of the nitrogenous substances and the fatty material from which the petroleum was produced. The salts found in these accompanying waters may well have been derived from saline deposits in which the decomposition of the animal remains took place. The first reaction tending towards the production of petroleum would probably be the splitting off of the glycerol from the fat acids, the latter then changing into hydrocarbons of the fatty and aromatic series (with elimination of carbon dioxide, carbon monoxide, and water), and the conversion of the former into acrolein, which would then give rise to hydrocarbons of the aromatic series. Zalozecki's assumption that the origin of ozokerite may be assigned to causes similar to those governing the formation of petroleum, would necessitate the occurrence of aromatic hydrocarbons in the former substance; experimental proof on this point is therefore requisite.

The hypothesis put forward by Ochsenius (preceding abstract) that the saline waters found accompanying petroleum have had a direct influence on the formation of hydrocarbons from animal remains, has to encounter the same objection as that of Zalozecki, namely, that the water may be present either entirely adventitiously, or result from the decomposition of the animal remains themselves in the manner described above. The action of the halogen compounds of potassium, sodium, and magnesium, upon fatty materials, would appear to be, as far as our present knowledge goes, too slight to rank as the chief factor in the production of petroleum; experiments to ascertain the precise result of treating fats with the saturated solutions of these substances at high pressures are, however, very desirable.

The fundamental objection held by the authors to the above-mentioned hypotheses, lies in the fact that such water as may be necessary to carry out the reactions resulting in the formation of petroleum or to form those supplies which commonly accompany petroleum, may be accounted for by the decomposition of animal matter in the process of conversion into petroleum, instead of being of extraneous origin.—B. B.

The Rectification of Petroleum Spirit. A. Veith. Dingl. Polyt. J. 282, 159—161.

APPARATUS FOR RECTIFYING PETROLEUM SPIRIT.

THE crude spirit obtained from the first distillation of petroleum usually boils below 150° — 160° C., and has a specific gravity of 0.750 to 0.760 (the Russian spirit being generally somewhat heavier). This product has little commercial value as such, owing to its odour, colour, and the considerable amount of oil it contains; the latter characteristic especially preventing its use as an oil solvent. By careful distillation through Linneman's or Le Bel's fractionating apparatus it may be split up into four products as follows:—

	Boiling Point.
1st spirit (ether)	30° — 55° or 60°
2nd spirit	60° — 80°
3rd spirit	80° — 100° or 110°
4th spirit	110° — 140°

On the large scale, distillation with a simple condenser fed with cold water is not sufficient to obtain more than a spirit free from oil; the boiling points of the distillates varying too much to render them valuable. A considerable advantage, however, is gained even in this case by the use of horizontal stills, as the available heating surface does not decrease during the distillation to the same extent as it does with the perpendicular form.

When an efficient fractionating apparatus, such as is described below, is employed, the heating surface of the still should be sufficient to evaporate five times the amount of the distillate obtained, the remaining four parts being condensed in the fractionator and running back into the still; thus with an hourly yield of 200 litres (boiling point, 40° — 100°), the heating surface of the still should be 3.5 square metres, the still being heated with dry steam at a temperature of 140° C.

By means of the fractionator shown in the Figure, spirits may be obtained containing only from 2 to 5 per cent. of the higher and lower fractions, boiling, with this exception, within the limits given above. Water, cold at first, is supplied through the orifice G at the bottom, passing through the tubes *a* and running off from A. When the first fraction is all off the cock *b* is opened, lowering the surface of the water to the level B, and thus reducing the condensing surface; at the end of the second fraction, cock 2 being opened, the water falls to C, and so on. The temperature may also be regulated by adjusting the supply, and at the close may be raised by admitting steam through the perforated tube F. The apparatus is connected with two horizontal stills having each a heating surface of 3.5 square metres in the ordinary way, and with its aid, spirits having a specific gravity of 0.640—0.650, or even as low as 0.625, may be obtained. Owing to the amount of sulphur contained in the crude petroleum the apparatus should not be made of copper.—F. H. L.

PATENTS.

Improvements in the Production of Coke for Foundry and other Purposes. F. J. Jones, Bedford. Eng. Pat. 19,501, November 29, 1890. 8d.

IN using the process previously patented (this Journal, 1891, 242) in which coking was effected by the passage of gases from the combustion of fuel from a separate producer, the coke produced has been found to contain sulphur and other impurities derived from the producer-gases.

It is now proposed to utilise the gases given off in the coking operation for this purpose. As the gases so obtained are more than sufficient to coke a similar charge, producer-gas is only necessary to start the cycle of operations in the first ovens of a series, the formerly wasted gases serving in turn to effect the coking of the remainder and of the subsequent charges.

To ensure the purity of the coke, the gases are led through condensers and purifiers, by which means ammonia and other by-products can be recovered. The purified gases are then passed through a reheater till raised to the required temperature, and finally introduced into combustion chambers or flues round the ovens. Here sufficient air is admitted to ensure almost perfect combustion, and the products are led into the ovens to effect the coking of the fresh charge.

In practice the purified gases are preferably reheated by mixing them with fresh gases from pure fuel in the producer, the fuel used being the "breeze" or small coke from a previous charge coked by this process, and consequently pure. To ensure production of pure coke in the ovens from the commencement, the producer should be charged at first with wood or charcoal.

By suitably timing the heats and intermediate operations, the process is rendered continuous.

The details of the plant are clearly illustrated by means of drawings attached to the specification.—D. A. S.

Improvements in and Apparatus for Distilling, more especially intended for Distilling Tar. F. Lennard, London. Eng. Pat. 844, January 16, 1891. 1s. 1d.

THIS patent is said to provide means by which the distillation of coal-tar can be conducted economically and expeditiously, and so as to obtain in a manner readily under control the different products of distillation, the heat of the vapours of distillation being employed to effect the partial heating of the materials to be distilled which in their turn assist the condensation of the vapours. The invention, although not restricted to the distillation of coal-tar, is more especially intended for the same. The tar to be distilled passes or is forced from the store tank into boilers in which the ammoniacal liquor separates, the tar having been previously heated by being forced on its way to the boilers through a series of condensers, so that the tar forms the condensing medium. It is then passed or forced through heated coils placed in an oven or sand-bath. By this arrangement the tar is heated to, or above, the point at which its vaporisable constituents required to be extracted would be given off in the form of vapour if not confined in the coils. It now enters a scrubber in which the volatile constituents vaporise and meet a current of steam, the pitch being deposited in the scrubber whilst the other constituents pass off by a pipe to the first condenser wherein the heaviest products (anthracene oils) deposit, the noncondensed vapours passing by a pipe to the second condenser wherein the next product (creosote oils) deposits and the vapours which are still uncondensed passing into the last condenser wherein the lightest products (naphthas) and the water are condensed.

The heating apparatus consists of a furnace with return flues, and above it a sand-bath in which are situated coils which are in communication with other coils contained in a chamber through which the products of combustion pass, and which the patentee calls the "economiser." The furnace is heated by means of liquid or gaseous fuel which the patentee prefers to use, although he does not restrict

himself to its employment. The scrubber forms a vertical tower provided with a series of tubular passages so arranged that the tar passes downwards in a circuitous manner, meeting a current of steam which carries off the more volatile constituents, the pitch which is thus formed depositing at the bottom of the scrubber. The condensers consist of vertical vessels provided with tubes and with outlets and inlets so arranged that the vapours pass inside the tubes, whilst the condensing agent (the tar) passes on to the outside of the tubes. "In the first condenser of the series the condensing agent may be the tar from the ammoniacal liquor separators, whilst in the others it may be the tar which is ultimately to be distilled." The tar to be distilled may be pumped through, say, the last condenser, and passes around the tubes and thence either direct by a pipe to the vessels in which the ammoniacal liquor is separated, or before passing to these vessels, it may be passed through another of the condensers. From the ammoniacal liquor separating tanks the tar is forced into the first condenser, then through the coils in the economiser, and finally through the coils in the oven or sand-bath. Thus the tar is heated to the temperature necessary to cause the vaporisable constituents to vaporise. The coils of the economiser and oven or sand-bath are preferably flattened, and to provide extended heating surface they may have fins on them, and there may be pipes or passages of refractory material extending from the furnace or flues (or both) to between the convolutions of the coils. Asbestos or slag wool and sand may be used to retain the heat. By regulating the speed at which the tar is passed through the apparatus the proper degree of heat for distilling is obtained irrespective of the temperature above that required for distilling the tar at which the furnace and the oven or sand-bath may be maintained. The specification is accompanied by seven sheets of drawings.—D. B.

Improvements in or connected with Ovens, Furnaces, or Retorts used for the Making of Coke or Charcoal, or for Distilling or Roasting Carbonaceous Matter, or otherwise subjecting Carbonaceous Matter to the Action of Heat. L. H. Armour, Gateshead-on-Tyne. Eng. Pat. 1579, January 28, 1891. 6d.

This invention substantially consists of means for supplying water or other liquid, or aqueous vapour, at a temperature lower than that of the effluent gases, and in regulated quantity, at or near the outlet for the gases escaping from the retort or oven above the charge.

It is claimed that the clogging or obstruction of the outlet by pitchy or tarry deposit is prevented, and that decomposition of ammonia is either partially or completely prevented.—D. A. S.

Apparatus for the Manufacture of Lamp-black Carbon-black. E. Binney, New York, U.S.A. Eng. Pat. 17,221, October 9, 1891. By Internat. Conv. March 9, 1891. 8d.

See under XIII., page 171.

A New or Improved Method of and Apparatus for Distilling Liquid Hydrocarbons. P. Dvorkovitz, "The Kerosene Company, Limited," and "The Tank Storage and Carriage Company, Limited," London. Eng. Pat. 13,089, August 1, 1891. 8d.

In carrying this invention into effect crude petroleum or other liquid hydrocarbon is passed from a tank to an oil superheater of any convenient construction, in which the oil is heated to a high temperature. It is then led to a retort where it is met by superheated steam, the temperature of which is higher than that of the heated oil. The latter is thereby split up into two portions, one consisting of oil vapour and the other of tar and precipitated matter. The mixed oil vapours and steam then pass through a large dome and are carried to a condenser. The tar is conveyed

to a second oil superheater, and the heated tar subjected to distillation in a retort aided by the injection of superheated steam, the vaporised part of the hydrocarbon being carried with the steam to a second condenser. The precipitated matter in the tar retort is collected or removed in any convenient manner.—D. B.

Improved Arrangement of Coke Ovens and Retorts for the Manufacture of Coke and Illuminating Gas. W. Creswick, Wakefield. Eng. Pat. 17,222, October 9, 1891. 11d.

In this invention the heated gases passing off from coke ovens are utilised for carbonising coal in closed retorts so constructed that gas and by-products are generated in the roasting of such coal and are collected for use elsewhere.

This is effected by ranging a series of coke ovens with exit apertures opening into a large receiving flue, and a series of retorts is also ranged, round any of which heated gases can be led before passing to the exit flue. The coke ovens are worked in the usual way, the escaping gases being coursed round the retorts by means of regulator dampers. The retorts are charged and drawn in the ordinary manner.

The claim is essentially for the combination of the ovens and retorts in this way, and for the special settings, two varieties of which are shown in detail in the sheets of drawings attached to the specification.—D. A. S.

Improvements in Retorts for the Carbonisation of Wood and other Vegetable Substances, and in the Drying of Manures, Sewage Sludge, and other Substances and Products. W. H. Bowers, Manchester. Eng. Pat. 17,623, October 15, 1891. 8d.

The retort used by the inventor is constructed with two or more parallel flues, extending in a longitudinal direction and lying one above the other. These are fed by the same furnace and eventually discharged into the same outlet. To make the description more intelligible, it is assumed that the retort is constructed with two flues. The space immediately above each flue forms a chamber through which the material to be operated upon is drawn by means of an endless chain, which is carried upon sprocket wheels, and is provided with bars at suitable intervals and of such width as to sweep the flow of the chamber. From the hopper where it is supplied to the retort, it is carried along and over the upper flue to its extremity, and it then falls into a space between such extremity and the sprocket wheel on to the chain as it runs below. The material is then drawn by the chain in the reverse direction along the lower flue until it falls over the extremity of that flue through an aperture provided for its discharge from the retort. The flues are connected by an elbow or external flue at the point most distant from the furnace. The gas driven off during the operation escapes by condenser pipes, and is dealt with in the ordinary manner.

By means of this arrangement the heat from a single furnace is utilised to heat both chambers, and the material as it is drawn through the lower chamber is exposed to heat coming from above as well as from below, with the result that labour and time as well as fuel are economised.

—D. B.

IV.—COLOURING MATTERS AND DYES.

Dyewood Extracts and their Manufacture. F. E. Mafat. Bull. Soc. Ind. Mulhouse, 1891, 361—452. (See also this Journal, 1889, 612—618.)

MEISSONIER, in 1829, initiated in France the manufacture of extracts for printing on woollens. This industry did not rise to importance until 1835.

In 1842—43 Panay succeeded in obtaining from logwood liquor crystals of a deep red colour, almost black on the surface, which were in fact hematein (oxidised hematoxylin) more or less pure. He arrived at this result by placing the rasped logwood in heaps and watering and turning it over periodically for several weeks. Varillat (of St. Hilaire) was the first in 1855 to adopt vacuum pans for the concentration of the weak liquors, their use being borrowed from the sugar industry. At present there are 44 works in Europe and 5 in America devoted to the production of wood extracts.

Campeachy or Logwood.—The introduction of logwood into Europe dates from the discovery of America by the Spaniards, who denominated the wood *palo campechío*. The tree (*Hematoxylon campechianum*) grows to a height of 12—15 metres, and the trunk alone is employed in dyeing. The wood is imported into Europe principally from Carmen (Lower California), the State of Campeachy in Mexico, Honduras, Yucatan, St. Domingo, Hayti, Guadeloupe, Martinique, Trinidad, Jamaica, and Cuba. The woods most esteemed for the manufacture of extracts are those from the island of Hayti; the ones most employed at Havre being Fort Liberty, Cape, Aquinus, St. Mark, and Monte Christi woods. The Jamaica woods, in yield of extract, are inferior to those of Hayti, both in quantity and quality; the colour is not so strong or the shade so good. The roots of the Jamaica wood are also imported. Whilst low in price they are very difficult to grind, and their yield is in every respect unsatisfactory. The woods from Laguna, Carmen, Honduras, and Yucatan, whilst belonging to the same family, give a different shade; the colour yielded is very fine, but wanting in depth, and these woods are not so economical in the production of blacks as the Hayti wood. The woods from Guadeloupe, Martinique, &c. are less esteemed, and, like those of Jamaica, are used only because of the scarcity of the Hayti wood.

Yellow Wood or Fustic (Morus tinctoria).—The yellow woods are mostly got from Mexico and the neighbouring States, the West Indies, and South America. The wood most valued is that from the island of Cuba; it is a hard, compact, and heavy wood of an orange-yellow colour. The wood most employed in the manufacture of extracts is undoubtedly that of Nicaragua, which is known as Corinto, from its port of export; it is a heavy close-grained wood of a fine yellowish-orange colour.

Young fustic (the French *fustet*) is a shrub (*Rhus cotinus*) the branches of which, sawn and stripped of their bark, are used in dyeing. The young fustic of America is held in good esteem. The colouring matter is reddish-yellow, readily soluble in boiling water, and tolerably rich in tannin. The colouring matter of young fustic has great analogy with that of Persian berries (*Rhamnus tinctoria*), and the extracts of the latter are frequently mixed with young fustic.

Red Woods.—Pernambuco wood (*Cesalpinia echinata*) comes from Brazil and Jamaica. It is a hard, compact wood, heavier than water, and its surface after long exposure to air is of a black-red colour. That from Paraibo is most valued. Nicaragua, Bahia, St. Martha, and Lima woods (*Cesalpinia brasiliensis*) come from Mexico, Nicaragua, California, the Philippine Islands, and Brazil. Amongst them, the St. Martha and Lima woods are most esteemed, as they approximate most closely to the Pernambuco wood in shade, but on account of their high price the cheaper Bahia wood is almost always used in the manufacture of Lima wood extract. Sapan wood (*Cesalpinia sapan*) is imported from India, Réunion, Ceylon, Siam, Manilla, China, and Japan.

It yields colours which have a considerable resemblance to those of the St. Martha wood; it is not so rich in colouring matter, but the shades produced are very bright. All these red woods appear to contain the same colouring matter named "*Bravilin*" by Chevreul, who first isolated it. The extracts of red woods, both liquid and solid, are frequently mixed with arsenious acid and tin salts to brighten or modify their shade. A well-made solid extract represents 12 times its weight of original ground wood. It may be remarked with regard to red woods that the heart of the wood alone is rich in colouring matter.

There are other red woods of which the colouring matter is insoluble or only slightly soluble in water, such as santal (*Pterocarpus santalinus*), caliatour, barwood, and camwood. Santal wood comes from Asia, Ceylon, Madagascar, Coromandel, Australia, and Indo-China; caliatour wood from Caliatour and Madagascar; and barwood and camwood from Sierra Leone. These woods, finely ground, are only used directly in dyeing, and are not applicable for the manufacture of extracts.

The introduction of aniline colours has led to a greatly diminished use of the red woods, notably those of Pernambuco, Lima, St. Martha, and Sapan.

Manufacture of Dyewood Extracts.—The manufacture consists of four distinct stages—(1), the ageing of the woods; (2), the extraction of the colouring matter; (3), the concentration of the liquors; and (4), the preparation of the solid extract. The wood, after grinding, is carried by means of an elevator to the upper floor, where the logwood is sprinkled with water and exposed in heaps for 24 to 48 hours, whilst the fustic goes direct to the extractors. The extracting vats have their opening on a level with the upper floor; they are conical in form and are made of oak or pitch-pine. They are arranged in sets (say of six vats), and after being charged with the ground wood, boiling water is circulated methodically from vat No. 1 to vat No. 6, and so becomes more and more charged with colour; it leaves the last vat at a strength of 2° to 2½° B., and passes as strong liquor to the stock vats and is ready for concentration. The wood receives three successive treatments with water, and becoming more and more exhausted the third course gives only a strength of 1° B. Finally the wood is subjected to a fourth treatment with water, and this last liquor is returned to vat No. 1, the whole of the vats having in the meantime been recharged with fresh wood. The vats are provided with a false bottom pierced with holes and covered by a wire-work netting held in position by a grating. There are manholes at the side for discharging the spent wood, and steam-pipes are provided for heating the liquors.

The strong liquors at 1½° to 2¾° B. are pumped into the concentrating pans and there evaporated to the required strength. Up to 6° B. the liquors are only considered as strong decoctions; above 7° B. they are looked upon as extracts. Extracts marking respectively 26°, 23°, and 6½° B. in the concentrators will be 30°, 27°, and 10° B. when cold. To make the pure dry extract, the liquor is carefully evaporated in the vacuum pan to a density of 45° B., which is the proper strength for making a good dry extract. The charge is quickly run out, before it has time to thicken, into wood or metal moulds.

In the German works closed vats (usually in sets of 10) are used, and the woods are extracted under a pressure of 1½ to 2 atmospheres.

The quality of the water used in making the decoctions is of the highest importance; it should be pure, clear, and soft, and if not absolutely pure, it should by preference be slightly alkaline. It is of importance to avoid the use of water containing iron, bicarbonate of lime, metallic salts, or excess of alkali.

Dyewood Extracts of Commerce.—Hayti logwood yields 25 per cent. of its weight of extract at 30° B., or 16½ per cent. of dry extract. The woods most commonly used at the present time are of inferior quality to the above and yield only 22 per cent. of extract at 30° B., or 14.66 per cent. of dry extract. The logwood extracts produced in the early days of the industry were pure products, containing only the extract of the wood itself. The competition amongst makers and the demand for cheap products has

resulted in the manufacture of logwood and fustic extracts admixed with cheaper mineral and organic bodies, such as molasses, glucose, quercitron bark, sumac leaf, divi-divi, turmeric root, chestnut extract or the ground wood, dextrine, &c. When such admixed bodies are liable to fermentation in presence of acids or alkalis it becomes a necessary precaution to add suitable neutralising substances. Several of the latter bodies serve at the same time to brighten the shade of the extract, whilst others, such as potassium ferrieyanide and alizarine orange are added to both logwood and fustic extracts to impart a colour which is quite factitious. The *molasses* are obtained from the sugar refineries at a strength of 42° B.; 100 kilos. of this correspond to 140 kilos. at 30° B. *Glucose* is prepared from potato starch by treatment with dilute sulphuric acid and subsequent neutralisation of the acid with chalk. *Quercitron bark* (*Quercus tinctoria*), is obtained from Philadelphia and Baltimore; 100 kilos. of bark yield 30 kilos. of extract at 30° B. or 20 kilos. of dry extract. *Sumac* (*Rhus coriaria*) is got from Sicily, Italy, the Tyrol, Dalmatia, Illyria, France, Spain, Portugal, and North America; it contains tannic acid varying in amount from 10 to 22 per cent. The decoctions of sumac are only prepared as required as they readily ferment, the tannic acid being converted into gallic acid. 100 kilos. of Sicilian sumac yield 75 kilos. of extract at 30° B., or 50 kilos. of dry extract. *Divi-divi* (*Casalpinia coriaria*) is obtained from the West Indies and Central America. Its contents in tannin varies from 18 to 45 per cent.; 100 kilos. of divi-divi yield 52 to 56 kilos. of extract at 30° B., or 35 to 37 kilos. of dry extract. *Turmeric root* (*Curcuma rotunda*) is obtained from the East Indies, China, and Persia, and contains 68 per cent. of colouring matter. It is used in the form of an impalpable powder, being added in this state to fustic extracts which are to be converted in dry extracts. *Chestnut extract* is prepared from the wood of the chestnut tree (*Fagus castanea*) which grows in abundance in Central and Southern France, in Italy, Corsica, Spain, and Portugal. The wood of very old trees contains 6 per cent. of tannin; young trees not more than the half of this. Chestnut extract is brown and astringent; at 20° B. it keeps well, but if weaker than this its tannic acid is readily transformed into gallic acid. 630 kilos. of chestnut wood yield 100 kilos. of extract at 30° B., containing usually from 22 to 25 per cent. tannin. *Dextrin* is potato starch rendered soluble by treatment with nitric or other acid and subsequent drying in a stove.

Commercial Extracts manufactured at Havre and Rouen.—There are two systems of manufacture; the first, in which the woods are extracted with water only; the second, in which the water used is charged with molasses. In the first system the pure decoction serves as a base to which the admixtures are subsequently added; in the second system the extracting tanks are charged, not only with the ground woods, but also with several of the admixed bodies that enter into the composition of the final product. The first system is to be preferred as being best adapted to the manufacture of products of unvarying composition. It is seldom that logwood extract at 30° B. is sold in the absolutely pure state; that sold as pure usually contains from 14 to 17 per cent. of molasses at 30° B. Similarly the dry extracts sold as pure are seldom such in reality. Usually they contain 3 per cent. of chestnut extract at 30° B. and 5 per cent. of molasses at 42° B. The commercial hemateine in powder is prepared from 100 parts pure logwood extract at 30° B. and three parts of chestnut extract at 30° B. The solid extract is dried by lying on shelves for several days and then ground in the mill. It forms an orange-red powder of good appearance and is packed in hermetically sealed cases, as contact with air changes its appearance. In the preparation of the lower grades of extracts by the first system the admixtures are added to the strong liquors in the evaporating pans. In the second system the only substances that are added to the extracting vats are molasses, chestnut extract or the ground wood, and sumac leaves. The "foots" from the clarification of logwood extract, the powdered gypsum, potassium, ferrieyanide, &c., are added to the strong extracts in the evaporating pans.

In the second system the chestnut is added as ground wood, and the sumac in the form of leaves, to the extracting vats.

The manufacture of logwood extracts for calico printers is uniform in all the works. The logwood liquor at 10° B. is allowed to settle for 20 to 25 days, and the clear liquor is then evaporated in the concentrating pans to a strength of from 15° to 30° B. as required. Nevertheless logwood extracts for printers often contain molasses; thus one frequently sold is prepared from 3,000 kilos. logwood liquor at 10° B., 630 kilos. molasses at 30° B., and 5 kilos. soda crystals, yielding 1,625 kilos. extract at 30° B.

Commercial Fustic Extracts.—Fustic extracts are seldom sold pure; with few exceptions the extracts, both paste and dry, are admixed with foreign matter to reduce their cost. A comparison of the price at which the "dry fustic extract, superior" is sold at Havre, and the cost of the wood itself, shows a margin too small to admit of the profitable manufacture of a pure product. Fustic of good quality (Corinto, Cuba, or Tuspan) yields 11 to 12 per cent. of dry extract, or 16 to 18 per cent. of 30° B. The commercial fustic extracts contain, as admixtures, molasses, glucose, and dextrine, which are added to the weak liquors before passing to the concentrating pans; whilst quercitron bark, sumac leaves, powdered turmeric root, and divi-divi are mixed with the rasped wood in the extracting vats. Sulphates of soda and zinc and alizarin orange are also added to modify or brighten the shade of the extract.

Sumac Extract.—For the manufacture of sumac extract the Sicilian sumac is preferred; the sumacs of Italy, the Tyrol, Illyria, Dalmatia, France, &c., are less suitable. Sumac extract is mixed with molasses and chestnut extract, &c. In the manufacture the process must be continuous, the liquors passing at once from the vats to the concentrating pans. Vacuum pans are the most suitable and the extract, when ready, should at once be put up in casks. Sicilian sumac, when carefully treated, yields 75 per cent. of extract of 30° B.; the Dalmatian and Illyrian sumacs yield from 65 to 70 per cent.

Residues.—The spent woods are available only for burning in the furnaces. The "foots" which settle from the clarified logwood liquors contain, when dry, 48 per cent. of colouring matter. They are utilised as admixtures in preparing low qualities of dry logwood extracts. Logwood extract at 30° B. is calculated as yielding 7½ per cent. of such deposit.

Valuation of Extracts.—The paper concludes with a description of the valuation of logwood extracts by comparative dyeing trials and by colorimetric comparison. This portion of the paper has been discussed in the note by M. Geigy, abstract of which follows this.—W. E. K.

Report on Mafat's Memoir on Dyewood Extracts. R. Geigy, jun. Bull. Soc. Ind. de Mulhouse, 1891, 357–360.

M. GEIGY, having been appointed to examine M. Mafat's paper (see following abstract) presented for Prize LXI. offered by the Mulhouse Society for "a practical method for determining the quantity of hematein contained in logwood and its extracts without recourse to dyeing or printing," reports that the memoir consists of two distinct parts; the one a very complete account of the sources of the various dyewoods and the manufacture of extracts from them; and the second a brief description of the methods of determining the amount of colouring principle in logwood extracts. With respect to the former part of the memoir, M. Geigy reports that it presents a sufficiently complete and reliable description of the manufacture of dyewood extracts; at the same time he points out certain inaccuracies and inconsistencies. Thus, whilst in one place the author states that in logwood extracts the whole of the hematoxylin has been oxidised to hematein, he quotes later that Erdmann has isolated hematoxylin from dry logwood extract; the latter statement being in consonance

with the reporter's experience. Again, the percentage of colouring matter in the dye extract is stated by the author at 84.7 per cent., which is very much too high a figure; this arises from the supposition that the portion soluble in alcohol is all due to hematein, whilst as a fact the greater part of the resins are also soluble in alcohol. In the reporter's experience not more than 10 per cent. of crystallisable hematoxylin is contained in logwood extract at 30° B. The colouring principle of logwood includes in addition to hematoxylin, and perhaps traces of hematein, a resinous non-crystallisable substance which is distinguished by its property of giving a black dye with wool mordanted with bichrome, whilst hematoxylin gives a pure blue shade.

The method given by the author for determining the amount of hematein in logwood extract is a colorimetric one, applied to a mixture of logwood extract with chestnut extract and molasses in certain proportions, such as are used in the Havre and Rouen works. The reporter points out that the method is useful only for extracts falsified in a similar way, and has no general application. He quotes instances of two classes of logwood extract quite different from the above; the one containing only molasses in addition to the logwood extract, and used in wool dyeing; the other consisting of pure logwood extract without any foreign addition whatever, the use of the latter pure extract increasing year by year. The reporter considers the method of comparative dyeing or printing trials to be the only one at present known that gives reliable information as to the value of logwood extracts.—W. E. K.

Action of Nitric Acid on Dimethylortho-anisidine. P. van Romburgh. Compt. Rend. 1891, 113, 305—308.

By the action of nitric acid on dimethylortho-anisidine Grimaux and Lefèvre obtained a product which melted at 135°, and to which they assigned the formula—

(Compt. Rend. 112, 727; this Journal, 1891, 692). The author finds, however, that this formula is incorrect, and that dimethylortho-anisidine, when acted on by nitric acid, behaves like other dimethyl-aromatic amines which he has examined. The product described by Grimaux and Lefèvre is in fact the nitrosamine of dinitro-monomethylortho-anisidine—

and can be formed also from dinitro-orthomethylanisidine obtained by boiling the corresponding nitramine with phenol. When dinitro-orthomethylanisidine is dissolved in nitric acid and treated with nitrous acid, the above product melting at 135° is obtained.—A. K. M.

β-Naphthaquinone Sulphonic Acids. O. N. Witt. Ber. 1891, 24, 3154—3157.

The oxidising agents, ferric chloride and potassium bichromate, usually employed for the preparation of β-naphthaquinone, cannot be used for the preparation of β-naphthaquinone sulphonic acid from amido-β-naphthol-β-sulphonic acid, as that compound, like the similarly-constituted nitrosonaphthol sulphonic acids, has an extraordinary affinity for the metals of the iron group, the salts thus produced being decomposable only with great difficulty. Nitric acid was, therefore, used: 10 grms. of amido-β-naphthol-β-sulphonic acid ("Eikonogen") were gradually added to 10 cc. of nitric acid of sp. gr. 1.2; the crystalline mass produced was drained on porcelain, and then dissolved in a small quantity of water, 6—7.5 grms. of golden-yellow needles of the quinone compound being obtained on cooling the solution to 0° C. They consist of the ammonium

sulphonate of β-naphthaquinone which is formed according to the equation—

This salt may be dried at 100°—110° without decomposing. The ammonia in it is not displaced by the action of dilute acids, but is removed by sodium hydrate, a sodium sulphonate being formed, which is decomposed with the production of a brown substance by excess of sodium hydrate. It is very soluble in water, less so in alcohol. It interacts in the cold with o-diamines, forming azine sulphonic acids. Sulphurous acid reduces it to the corresponding quinol compound, which may be conveniently prepared from amido-β-naphthol-β-sulphonic acid by acting on the same with the calculated quantity of bromine and adding the solution of the quinone compound so produced to an excess of sulphurous acid. The ammonium salt of β-naphthaquinolsulphonic acid thus obtained crystallises in snow-white plates, is very soluble in water, reduces silver salts, is unacted upon by nitric acid of less density than 1.2, but is reconverted by acid of that or of greater density into the quinone compound; when oxidised in the presence of a para-diamine it yields a dye of the indophenol class; and, unlike o-dihydroxybenzene, interacts with diazo-compounds forming azo-dyes which have the property of combining with metallic-oxide mordants (Eng. Pat. 2499 of 1889; this Journal, 1890, 172).

The β-quinone compounds of naphthalene α- and β-sulphonic and γ- and δ-disulphonic acids, form yellow crystals; that of the α-sulphonic acid appears to be uncrystallisable. All these compounds are reduced to o-dihydroxy compounds by sulphurous acid.—E. B.

α-Naphthol-α-Sulphonic Acid. O. N. Witt and H. Kaufmann. Ber. 1891, 24, 3157—3163.

α-NAPHTHOL-α-SULPHONIC acid is industrially prepared from naphthionic acid by two methods, namely, by diazotising and boiling with dilute sulphuric acid and by fusing with sodium hydrate under pressure. The first method yields a red uncrystallisable product, the second a grey crystalline mass which turns brown on exposure to air. The two products, moreover, differ considerably in regard to the solubility and crystalline form of their azo-derivatives. The authors, who have made a study of the two preparations with a view of explaining these differences, find that each product consists chiefly of α-naphthol-α-sulphonic acid, but that the product obtained by the diazo reaction contains a compound (not isolated) which prevents it crystallising, while that of the fusion process contains an isomeride of α-naphthol-α-sulphonic acid as well as α-naphthol. This was proved to be the case by preparing the phenylazo-derivative of each product, the sodium sulphonate obtained by the second method being, however, previously purified from α-naphthol by extracting with ether, after acidifying with acetic acid. The respective azo-dyes obtained were repeatedly recrystallised until they were undistinguishable from each other. They were then reduced with acidified stannous chloride in the manner devised by Witt (this Journal, 1889, 276) the same amidonaphthol-sulphonic acid, $\text{C}_{10}\text{H}_7 \cdot \text{OH} \cdot \text{NH}_2 \cdot \text{SO}_3\text{H} + \text{H}_2\text{O}$, being obtained from each.

A very characteristic derivative of α-naphthol-α-sulphonic acid, and one which is readily obtained, even from a very crude preparation of that substance, is the β-nitroso compound. This is best prepared from technical α-naphthol-α-sulphonic acid (24.6 grms.) by dissolving in water (300 cc.), adding concentrated hydrochloric acid (19 cc.) and then gradually, the mixture meanwhile being well cooled, a solution of sodium nitrite (6.9 grms.). The free nitroso-sulphonic acid which quickly separates out is collected on a filter, pressed, and recrystallised from dilute hydrochloric acid. It is thus obtained in lustrous, golden-brown crystals containing $3\frac{1}{2}$ H₂O. It is easily soluble in water and alcohol; possesses a strongly acid reaction; dissolves in concentrated sulphuric acid with an orange colour, turning yellow on dilution; hydrochloric acid reduces its solubility in water to a remarkable extent, nitric acid converts it into dinitro-naphthol. It forms two series of salts, acid and neutral;

the latter in general crystallise well. The neutral ammonium and sodium salts in solution have an intense purple colour, the acid sodium salt forms orange-red needles or prisms which dissolve readily in pure water, but with difficulty in saline solutions. The acid barium salt is very sparingly soluble, but may be crystallised from a large quantity of water in scarlet crystals containing 3 H₂O. The cobalt compound has a red, and the ferrous iron compound a green colour, as O. Hoffmann has already pointed out (Ber. 18, 46). β -nitroso- α -naphthol- α -sulphonic acid readily interacts with amines, &c.: with ammonia at 160°—180°, with the hydrochlorides of aniline, phenylhydrazine, hydroxylamine at lower temperatures, yielding compounds of complex constitution; with aniline and zinc chloride yielding naphthaquinone-dianilide. Its most striking interaction, however, is with *o*-diamines in aqueous solution, the sulphonic acid group being split off and scarlet dyestuffs of the Eurlidine class being formed. The colour base of that obtained from *o*-toluylenediamine crystallises in golden-yellow needles melting at 257°; sufficient of it was not obtained for analysis. Acidified stannous chloride, and acid sodium sulphite reduce the nitroso-compound to the above-mentioned amido-compound. This is oxidised by nitric acid (see preceding abstract) to β -naphthaquinonesulphonic acid, the sodium salt of which is easily soluble in water but quite insoluble in alcohol. Sulphurous acid reduces the quinone to the corresponding dihydroxy-compound.—E. B.

The Action of Nitrous Acid on Tetramethyldiamidobenzophenone. W. Herzberg and M. Polonowsky. Ber. 1891, 24, 3197—3201.

E. Bischoff (this Journal, 1888, 742) has stated that the product of the action of nitrous acid on tetramethyldiamidobenzophenone is a nitroso compound of the formula—

The authors have re-examined the product, and interpret the reaction by which it is formed in the manner indicated by the following equation—

the analysis and properties of the body in question according with this view. The nitrosamine thus produced crystallises from alcohol in yellow plates, melting with decomposition at 182°—183°. On heating with concentrated hydrochloric acid, it is decomposed with evolution of gas into trimethyldiamidobenzophenone, a substance crystallising from alcohol in pale-yellow plates, which melt at 203°—204°. The latter compound in its properties closely resembles the tetramethyl compound; its acetyl derivative melts at 145°; on fusion with ammonium chloride it yields a dye of similar shade to ordinary Auramine.

Nitrous acid has a similar action on the leuco-bases of Malachite green and Crystal violet, a nitro-compound in addition to a nitrosamine, being obtained from the leuco-base of the latter dye.

Tetramethyldiamidodiphenylmethane (1 mol.) in hydrochloric acid solution, is acted upon by nitrous acid (from 2 mols. of NaNO₂) with formation of *p*-nitrodimehylamine, a 25 per cent. yield of this substance being obtained.

The agreement of Bischoff's analytical numbers with those required for the nitroso-derivative of tetramethyldiamidobenzophenone is explained by the presence of unaltered ketone-base in the precipitate obtained on rendering alkaline the crude solution of trimethyldiamidobenzophenone-nitrosamine.

Wichelhaus (this Journal, 1886, 318) has previously prepared trimethyldiamidobenzophenone. As, however, this chemist has described it as possessing different properties from those observed by the authors, and as, moreover,

Wichelhaus's description of the leuco-base of (penta-) methyl violet (from which he prepared it) does not agree with that of O. Fischer and others, the authors consider it probable that Wichelhaus's preparation was mixed with tetramethyldiamidobenzophenone, which would be produced by the decomposition of the leuco-base of hexamethyl violet intermixed with the pentamethyl compound.—E. B.

Studies in the Induline Group III. O. Fischer and E. Hepp. Annalen, 266, 249—263.

Benzindulines.—The authors previously succeeded in showing that the rosindulines are derivatives of the well-known naphthophenazine—

and they now show that an analogous relation obtains for the benzindulines and phenazine—

Operating with phenylinduline (Ann. 262, 256) the authors obtained from it by heating with glacial acetic acid and dilute sulphuric acid for about six hours at 200° C., besides aniline three decomposition products, the largest quantity of which consists of a brown crystalline substance which is hydrated phenylinduline—

This base melts at about 218° C., heated to a higher temperature it is converted into carbazol fluorindine, which substance is already contained in small quantities in the original phenylinduline melt. On heating the base with concentrated hydrochloric acid aniline is separated and a hydroxy derivative of the base is obtained. This hydroxy-derivative is soluble in alkalis.

The original phenylinduline is heated to 170° with hydrochloric acid, and on filtering yields a red-brown filtrate containing two new compounds. One is a hydroxy-compound of the formula C₁₅H₁₁N₂O₂, the other is benzindone, C₁₅H₁₂N₂O. They may be separated by addition of an alkali and subsequent filtration, when the hydroxy compound remains in solution, whilst the benzindone remains insoluble on the filter. From the alkaline solution the hydroxy-compound may be isolated by means of acetic acid and subsequent extraction with ether, from which it is obtained in the form of reddish-yellow crystals. From alcohol or benzene it crystallises in the form of beautiful brown-yellow prisms or tables. The substance possesses the properties of both a base and a phenol. It melts at about 280° C. The authors consider this compound to be either a hydrate of benzindone or a derivative of hydroxy-phenazonium—

From the properties of the compound in question the authors conclude the second of these formulae to represent its constitution.

The benzindone, $C_{18}H_{12}N_2O$, which is insoluble in alkalis, crystallises from alcohol in well-formed plates with metallic lustre. The substance is soluble in acids, dissolving in strong sulphuric acid, and forming a green solution; by this behaviour it proves itself to be a true analogue of the rosindones. This is further proved by the fact that whereas rosindone on dry distillation with zinc-dust yields naphtho-phenazine, benzindone under the same conditions yields the corresponding phenazine—

Decomposition of Amidophenylinduline with Acids.—This induline, $C_{25}H_{18}N_4$, contains a primary amido-group, the position of which has not been yet ascertained. The authors prove that in treating this induline with acids neither phenylenediamine nor benzindone is formed, so that the composition of this induline is best expressed by the formula—

than by the formula of Schultz and Juius.

Amongst the products of the decomposition of amidophenylinduline with acids, a compound, $C_{18}H_{12}N_2O_2$, was formed, which is soluble in alkalis, and this is evidently an amido-derivative of the already described hydroxy-compound, $C_{18}H_{12}N_2O_2$. From the strong fluorescence of the solutions of this compound, as well as from its solubility in water and the pink colour of its salts, the authors consider that it belongs to the safranines. The formation of this substance is supposed to be expressed by the equation—

In studying the indulines, the safranines prove to be always their inseparable companions. Safranines, rosindulines, indazines show very great similarity (Ann. 262, 262—263), so that it is frequently a matter of some doubt whether a certain compound is to be classed amongst the indulines or amongst the safranines. This is explained by the fact that the paraquinone-azine group of the indulines, either by hydration or by oxidation, is readily converted into the orthoquinone group of the safranines.

Action of Aniline upon Amidophenylinduline.—On heating the hydrochloride of the induline, $C_{24}H_{18}N_4$, with two parts of aniline for some hours at $160^\circ C$, two new indulines are obtained, which the authors believe to be phenylamido-phenylinduline, $C_{30}H_{22}N_4$, and amidophenylamidophenylinduline, $C_{36}H_{27}N_5$. The two indulines may be separated by means of hot alcohol, in which only the first-named is soluble. The induline, $C_{30}H_{22}N_4$, can advantageously be

obtained by heating a mixture of phenylamidoazobenzene (136 grs.), aniline (140 grs.), aniline hydrochloride (65 grs.), and alcohol (500 grs.), at about $160^\circ C$ for 12 hours. The induline obtained is purified by recrystallisation from hot alcohol. The melting point of the base is at from 245° to $250^\circ C$.

The induline, $C_{36}H_{27}N_5$, is identical with a substance previously obtained by Witt and Thomas, and is the most insoluble of all known indulines. It is contained in the ordinary amidoazobenzene, melts in very small quantities only, but by employing the azobenzene melt it may be obtained in considerable quantities. The base of this induline melts at from 286° to $288^\circ C$.

To determine the molecular weight of phenylinduline the authors used Raoult's method. The results of the experiments are in favour of the formula, $C_{24}H_{17}N_3$. The bases of the indulines, $C_{24}H_{17}N_3$, $C_{30}H_{22}N_4$, and $C_{36}H_{27}N_5$, are too insoluble to allow of the estimation of their molecular weights by the above process.

The authors, whilst promising further data, especially on rosindulines, point to the fact that these colouring matters are coming more and more into prominence, and will very probably soon acquire great importance in the coal-tar colour industry.—C. O. W.

Preparation of the Dinitrophenol, $C_6H_3(OH)(NO_2)_2$ 1:2:4 and some Properties of the Diamidophenol. B. Reverdin and C. de la Harpe. Chem. Zeit. 1891, 16, 45—46.

For the preparation of considerable quantities of dinitrophenol the authors made use of the following method:—400 parts of sulphuric acid $66^\circ B$. are heated to 110° , and 200 parts of phenol are added, and the mixture is kept heated to 130° — 140° for five hours. The product is mixed with 600 cc. of water, and then a mixture of 800 grms. of nitric acid $36^\circ B$. with 575 cc. of water is slowly added, care being taken that the temperature does not exceed 40° — 50° . The mixture is allowed to stand for 24 hours at the ordinary temperature, and afterwards is slowly heated for three days on a water-bath, then allowed to cool, and filtered. The cake of crystals produced consist almost entirely of pure dinitrophenol. To obtain the chemically pure product it must be beaten twice with 21 parts of water. With these quantities 100 parts of dinitrophenol can be obtained. The authors point out that the diamidophenol obtained from this nitro-body by reduction possesses the property of giving to fabrics, when oxidised, an intense brown colour which is fast to light and soap. The oxidation can be produced by a dilute solution of chlorate of sodium mixed with a very small quantity of ammonium vanadate and by other metallic salts. The wool or cotton is put into a hot solution of the hydrochloride of the diamidophenol and the oxidising agent added.

The hydrochloric acid salt gives colour reactions on being heated with aromatic amines. For example, 1 part of the salt heated with 10 parts of aniline gives a dark blue dye, from which a blue dyestuff can be isolated. Azophenine is obtained as a by-product in this reaction.

The authors have paid particular attention to the behaviour of the hydrochloric acid salt of the diamidophenol as a photographic developer, and they find that its solution in water with 5—6 parts of sulphite of sodium acts on exposed plates with energy, but they have not yet been able to satisfactorily control its working. The body loses this property when mixed with a small quantity of bromide of sodium.—E. C. C. B.

PATENTS.

Improvements in the Manufacture of Colouring Matters.

H. H. Lake, London. From "A. Leonhardt and Co.," Mühlheim-on-the-Maine, Germany. Eng. Pat. 2805, February 16, 1891. 4d.

If β -naphthalene disulphonic acid be converted into the dinitro-compound and this reduced, a diamido-compound is obtained which on diazotisation combines with phenol. The dyestuff thus formed is, however, sensitive to alkalis.

By methylating, ethylating, or benzylating the product it is rendered fast to alkalis, the process being similar to that described in Eng. Pat. 3994 of 1887 (this Journal, 1888, 319).—T. A. L.

Improvements in the Manufacture of Azo Dyes. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 3439, February 25, 1891. 8d.

This is an extension of Eng. Pat. 13,235 of 1890 (this Journal, 1891, 760) and refers to the sulphonation of the dyestuffs there mentioned. The specification also describes the preparation of a number of dyestuffs from tetrazo-compounds by combining these with α -naphthylamine or α -amidonaphthol ether and either with or without sulphonation, combining these products, after diazotisation, with a phenol, naphthol, dihydroxynaphthalene, amine, amidonaphthol, or their sulphonie or carboxylic acids, if necessary, sulphonating the final product. The colouring matters dye unmodified cotton in various shades, such as brown, green, violet-blue, and black, those obtained from the naphthol ethers giving bluer or greener shades than those from naphthylamine.—T. A. L.

Erratum.—In the January number of this Journal, page 27, col. 2, in the first formula given for $(\text{NOH})^{(3)}$ read $(\text{NOH})^{(4)}$; and in paragraph 4, for $[\text{CH}_3 : \text{NH}_2 : \text{NO}_2 = 1 : 3 : 5]$ read $[\text{CH}_3 : \text{NH}_2 : \text{NO}_2 = 1 : 3 : 4]$.

V.—TEXTILES: COTTON, WOOL, SILK, Etc. PATENTS.

Improvements in Fabrics for Sacks or Bags. P. B. Hollick, London. Eng. Pat. 16,801, October 21, 1890. 4d.

This invention refers to the introduction of some heavy and stout warp or weft threads into sackings or baggings which are made of jute, these being interwoven with the said threads at intervals throughout the width or length of the cloth. The heavier warp or weft threads may also be made of material other than jute, namely, flax, cotton, leather, wire, Manilla, or any other kind of hemp, the object being to give additional strength without materially increasing the weight.—H. S.

Improvements in Self-registering Apparatus for Measuring the Sensibility and Breaking Strain of Paper and other Light and Flexible Material. F. Lennig, London. Eng. Pat. 18,431, November 15, 1890. 6d.

This invention cannot be suitably described without reference to the drawing.—J. C. C.

Improvements in or applicable to Machines for Scouring and Washing Wool and other Fibrous Materials. J. McNaught and W. McNaught, Rochdale. Eng. Pat. 19,878, December 5, 1890. 6d.

This invention relates to an improved construction of scouring machines, whereby the sand and other heavy foreign substances in the scouring liquor are separated therefrom and allowed to settle in a detached tank. The liquid is caught from the squeezing rollers and elevated to an auxiliary tank arranged alongside the washing tank, by means of a rotary wheel having scoops. The liquor drains from the auxiliary tank to the washing tank through a suitable aperture or communication pipe, while the heavy substances settle and are retained in the said tank.—H. S.

Improvements connected with the Manufacture of Yarns and Fabrics from Waste Silk, and with the Washing of the Resulting Material or of the Clothing Produced therefrom. B. Beyer, Grossenhain, Germany. Eng. Pat. 12,817, July 28, 1891. 4d.

This process, it is claimed, relieves all waste raw silk of the offensive smell which it is well known to retain, owing to the bast adhering to it, and thus enables clothing to be manufactured therefrom at a cost not expected to greatly exceed that of woollen underclothing. The yarn is boiled for about 15 minutes daily in a bath prepared with oil soap for a number of days. Removed from this bath the material is washed in cold water and conveyed into a steam-bath, where it is left for several hours, after being sprinkled with a thin layer of chloride of sodium. After a repeated steaming and washing the material is bleached or conveyed into a drying chamber, a moderate temperature being maintained. The whole operation is repeated daily for preferably at least 20 days, after which the material is suspended in a course of water for 24 hours. The colour of the material is then a dull white, and it is perfectly inodorous. The material is then ready for manufacture, and the finished articles should be washed in cold water containing permanganate of potash, and steeped in a weak solution of chloride of sodium, the same solution being used for washing the clothes when worn.—H. S.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Orange in Calico and Wool Printing. Oester. Wollen und Leinen-ind. December 15, 1891.

THE method for the production of orange in calico printing, which has been in use for a long time, and is still largely made use of, is based on the fact that lead acetate and potassium chromate yield yellow lead chromate, which on treatment with lime becomes orange. One can also proceed in such a way that the orange lake is prepared ready and then printed with blood albumen, or by printing the material with a thickened lead salt, chroming, and then passing through a bath of caustic alkali. Two and a half parts of lead acetate are precipitated with one part potassium bichromate in a sufficiently dilute solution, the precipitate washed and boiled with milk of lime, well washed, filtered, and pressed, and about 400 grms. orange lake thickened with 600 grms. albumen solution, printed and steamed. If the orange is required yellower, one part of the orange lake is replaced by one part of yellow lead chromate.

On printing the lead salt, about 300 grms. lead acetate or nitrate must be taken per litre of thickening, printed and steamed, or aged, passed through ammonia, chromed according to the size of the pattern with the necessary quantity of bichromate, and then passed through a boiling concentrated milk of lime solution.

Another orange is produced with *Alizarin orange*, which gives a brilliant lake with aluminium salts. Either aluminium acetate, nitrate, or sulphocyanide may be used, with the addition of calcium nitrate or acetate, printing on material which has been impregnated with Turkey-red oil, steaming and soaping. 550 grms. thickening and 150 grms. Alizarin orange R (20 per cent.) are well mixed, and 50 grms. acetic acid 9° Tw. (30 per cent.), 200 grms. aluminium acetate at 10° B., and 50 grms. calcium acetate at 10° B. are added. The colour should be printed immediately after its preparation. Alizarin orange may, for instance, be turned more yellow by the addition of lead acetate with subsequent chroming. A second method is to mix with it some Gallacetophenone or Alizarin yellow (B.A.S.F.). This yellow is fixed by means of aluminium sulphocyanide and calcium acetate, and agrees perfectly well with Alizarin orange.

Another orange, which up to the present has not had much application, is *Acridine orange* (L.). This is fixed by means of tannin on cotton material, and finally the latter is passed through an ordinary bath.

With *Persian-berry extract*, or *Flavin* and a tin-salt, very fine oranges may be obtained; but these, as a rule, are not fast to soaping.

Lately, a new orange for printing, under the name of *Diamond orange* (Bayer), has been brought out. It is a reddish-brown paste, which has the advantage over Alizarin orange of not settling at the bottom of the casks like the latter, and can consequently be stirred better. A further advantage lies in the fact that the printing colour can be preserved for some time without losing any of its intensity. Alizarin orange, on the other hand, after a very short exposure loses as much as 50 per cent. of its colouring power, even when sulphocyanide is employed instead of aluminium acetate.

The printing colour is best prepared by mixing well 740 grms. of thickening, 200 grms. of Diamond orange, and 60 grms. of chromium acetate.

The chrome lake produced with *Diamond orange* on oiled material is redder than the one obtained with Alizarin orange and alumina, but can be turned yellow with Diamond yellow (Bayer), Alizarin yellow (Hoechst), or Diamond flavine (Bayer), as all these colours, like Diamond orange, may be fixed with chromium acetate. A shade similar to Alizarin orange may be obtained as follows:—787 grms. thickening (containing acetic acid), 100 grms. Diamond flavine G (Bayer), 66 grms. Diamond orange, and 47 grms. chromium acetate at 20° B., are mixed together. This is printed on material impregnated with Turkey-red oil, steamed one hour, without pressure, passed through a alk bath, and soaped about 20 minutes at 50° C.

In wool-printing, *Alizarin orange R* gives an orange fast to soaping when produced as follows:—110 grms. of Alizarin orange R (20 per cent.), 590 grms. of thickening, 40 grms. aluminium sulphate dissolved in 140 grms. water, 20 grms. oxalic acid dissolved in 50 grms. water, and 50 grms. glycerin at 28° B., are mixed together. The colour is developed on prepared wool by means of steaming, washing, and soaping.

Of other colours, *Croceine orange* and *Orange II.* (B) are much employed in wool printing. Both give fiery shades by dissolving in water and acetic acid and thickening with gum-water, printing on chlorinated wool, then steaming and washing well. The proportions are about 1—2 grms. colouring matter, 8—9 grms. acetic acid at 6° B., 30 grms. water, and 60 grms. gum water.

The Application of Coal-Tar Colours in Paper Dyeing. A. Beaimann. *Färb. Zeit.* November 5, 1891.

For several years coal-tar colours have been largely used in this branch of industry, though formerly, in the manufacture of paper, mineral and vegetable colours were used almost exclusively. As in the dyeing of textile fabrics, so in this case it is chiefly on account of their easy application and their brilliant colour-effects that they have replaced the duller mineral and vegetable colouring matters in comparatively so short a time.

In paper dyeing there are two separate methods of applying the colours: first, surface dyeing; and secondly, the dyeing of the pulp itself. By the former process, in the manufacture of the so-called enamelled paper, the colours are mixed with water and starch paste, dextrin, &c. For highly-polished enamelled paper, the colours are mixed with kaolin, artificial barium sulphate (blanc fixe), or other similar products, and fixed on the surface of the paper with glue or gelatin.

Instead of these mixtures the general method, instead of using the colours themselves, is to employ colour lakes. By this means a more even surface is obtained with the colour. The colour mixture obtained by either of the above two methods is brushed on to the paper by means of either hand brushes or machine brushes, and then worked up for a higher polish.

The second process is the dyeing of the paper pulp. In order to render the following description more comprehensible, the author first follows up the method of the manufacture of the paper. The paper, according to its future use, is manufactured from linen, hemp, cotton, or jute rags, or from esparto grass, wood shavings, straw, wood cellulose, or straw cellulose. Better qualities, are, however, almost exclusively manufactured from rags. This raw material, after having been thoroughly ground and disintegrated in a paper mill, is bleached and then glued with colophonium and resin soap, prepared with caustic soda or potash with the addition of aluminium sulphate, through which treatment the precipitation of insoluble aluminium rosinate on to the paper fibre takes place. After this treatment the paper pulp is dyed, and then worked through the paper machine into rolls of paper.

The same property which vegetable and animal colouring matters possess, of forming insoluble or difficultly soluble colour lakes with certain metallic salts or organic acids, is also possessed to a certain extent by aniline colours. The properties of vegetable colours are made use of in paper dyeing, in so far that the paper pulp is saturated with the solutions of such bodies as are suitable for producing a colour lake with the colouring matters applied. Aniline colours, the application of which in paper dyeing has become so general on account of their many advantages, are usually employed as such—i.e., in concentrated solutions—in spite of the fact that they possess the property of forming colour lakes, by which latter a saving of colouring matter is effected, and, besides, the waste water is free from colour—often a serious question in the manufacture of paper. The reason of this is because the proper method of dyeing paper is not known in the trade.

This method of dyeing is also to be recommended because the colouring matter becomes evenly distributed in the paper pulp, however complex its composition may be, and combines very firmly with the fibre by reason of the adhesion. Through the presence of the rosin glue, which possesses an especial affinity for colour lakes, the combination becomes still firmer, and the water remains colourless, whether the material was glued before or after the dyeing. When this method of dyeing is used, it is advisable first to make small dyeings, because the colour lakes, as a rule, give rather different shades from the directly applied colours.

For precipitating the colouring matters, both the precipitants and the colours are made in fairly concentrated solutions; the colour solution is first added to the paper pulp, and then to the precipitating agent, after a thorough stirring.

Basic colours are precipitated by *tannin*.

Lead Acetate or *Barium Salts* in aqueous solution are used for precipitating Ponceaux and almost all azo-colouring matters. In the application of lead acetate, the aluminium sulphate of the rosin glue undergoes double decomposition, which, however, has little influence in the dyeing if the lead acetate solution is added gradually. By the formation of insoluble lead sulphate, the otherwise soluble lead salts are prevented from being carried away by the waste water, and in this way much inconvenience is obviated.

Resorcinol Colouring Matters, such as eosin, phloxin, &c., are precipitated most profitably with lead nitrate, or better with lead acetate; this latter can be prepared by treating sugar of lead with litharge for some time, or by adding ammonia to the sugar of lead solution until a permanent precipitate is formed. Besides the above-mentioned compounds for producing colour lakes from aniline colours, there exists a whole series, such as stannous chloride, calcium and magnesium chloride, acid and neutral salts of the alkalis, &c.—especially, however, aluminium salts. In glued paper pulp there is always an excess of aluminium sulphate present, and with such colours as are very easily precipitated, its presence is sometimes detrimental rather than useful. The necessary quantity of the precipitating agent varies according to its quality and to the colouring matter, and can be determined at the first trial with it. The price of the tannin and the lead salts, compared with that of the colouring matter saved by their use, is infinitesimal.

To see whether the whole of the colour has been precipitated it is necessary to take out a small pattern of the pulp, press it, and observe whether the water which runs out is coloured. If it should be coloured the precipitation is not yet complete, and consequently more precipitating agent must be added.

For deep shades of paper this method of dyeing offers the great advantage over the surface dyeing, of preventing the waste of unused colouring matter. For the preparation of certain kinds of paper, full shades can only be obtained by this method, and these productions are very much sought after.

Paper dyeing would to-day stand on an equal level with textile dyeing if more attention had been paid to this branch of industry. In spite of the above mention of the more economical yield of aniline colours, there are up to the present but a few of these colouring matters which can be applied in paper dyeing.

PATENTS.

Improvements in Printing Calicoes and other Woven Fabrics, and in Apparatus therefor. J. V. Hulme, Manchester. Eng. Pat. 1799, January 31, 1891. 8d.

IRREGULAR patterns, especially in indigo, suitable for the Indian, Chinese, Japanese, and African markets, are printed on calico by wooden rollers wrapped with ropes, chains, wire-netting, matting, &c. or partly covered with projecting pieces of india-rubber or of lead of various sizes. The printing-surfaces may also be formed of nails, screws, pegs, or pins with regularly or irregularly shaped projecting heads, either employed alone or interspersed with pieces of lead, roping, &c. Tufts of bristles arranged in an irregular manner may also be used. The effects may further be varied by passing the cloth *c* over two rollers *l* (see Figure) furnished with projecting strips of india-rubber, or of other suitable material, and revolving in water-troughs *m*, prior to printing with the roller *a*.

CALICO PRINTING APPARATUS.

After printing, the cloth is exposed to the air to oxidise the indigo and is then washed. Sometimes, in order to produce a blurred or clouded effect, the calico is brushed or sprinkled with water immediately after being printed. When a dark indigo ground with a pale indigo pattern is required, the cloth is first dyed with indigo and then printed in the above-described manner with a discharge solution.—E. B.

Improvements in the Construction of Machines for Printing Calico and other Woven Fabrics on both Sides. W. Buckley, Manchester. Eng. Pat. 1996, February 4, 1891. 6d.

The adjustable sliding bearings and adjusting screws of a duplex printing machine are arranged diagonally in opposite directions, instead of vertically as hitherto. The bowls can, consequently, not only be raised and lowered as usual, but can be brought very close together (when the machine is in action) or separated (to allow access for the occasional arrangement of the printing blankets and wrappings) as required. A more exact "register" of the pattern on the two sides of the fabric than was formerly possible can thus be obtained.

The printing rollers are adjustable in a radial direction as usual.—E. B.

Production of Azo-Colours in Discharge-printing on Indigo Dyed Fabrics. O. Imray, London. From the "Farbwerke vormals Meister, Lucius, und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 2818, February 16, 1891. 6d.

INSTEAD of adding to the thickened solutions of diazo-compounds an alkaline chromate and passing the cloth, printed with such a mixture, through an acid bath, to liberate chromic acid and effect the discharge of the indigo, as described in Eng. Pat. 7522 of 1890 (this Journal, 1891, 924), potassium ferricyanide is added and the printed cloth passed through an alkaline bath. The blue-dyed cloth is prepared with an alkaline solution of β -naphthol (29 grms. in 25 cc. of caustic soda solution at 22° B. and 200 cc. of water) and oleine (50 grms. of 50 per cent. quality per litre), and the following mixture, for example, printed on it for a red discharge:—83 grms. of *p*-nitraniline N ("a mixture of $\frac{15}{100}$ molecules of *p*-nitraniline and $\frac{15}{100}$ molecules of sodium nitrite with 5 per cent. of nitrite in excess of the theoretical quantity"), 572 cc. of water, 300 grms. of paste thickening, 45 cc. of hydrochloric acid at 22° B., 300 grms. of potassium ferricyanide, and 60 grms. of sodium acetate. After printing the cloth is passed through a solution of caustic soda of 5°–10° B. at 50°–60°, and is afterwards washed or soaped and dried. The above method has the advantage of allowing all diazo-compounds to be employed, whereas the process with chromic acid only admits of the employment of diazoazobenzene, other diazo-compounds not resisting the action of chromic acid.—E. B.

Improved Machinery for Dyeing Textile Materials in Hanks. E. Decock, Roubaix, France. Eng. Pat. 7511, April 30, 1891. 11d.

THE hanks are placed on bearers which are carried horizontally a little above the dye-vat, on two sets of endless chains furnished with projecting abutments for their support. The first set of chains conveys the hanks rapidly through a portion of the dye-bath, thus opening them out and allowing "the dye to come in contact freely with all parts," and then delivers them to the second set, which travels more slowly "in order to ensure a gradual and enduring action upon the material being dyed." From the latter set of chains the bearers are taken by a series of vertical and horizontal endless chains and carried upwards over the vat to the front of the same, for the purpose of again passing the hanks through the bath, this being repeated as many times as is necessary. The hanks are conveyed through the bath without rotary motion, but in passing along the overhead system toothed pinions on the ends of the bearers come into gear with toothed racks, so causing the hanks to alter their position upon the bearers before the following dip. Three sheets of drawings accompany the specification.—E. B.

Improvements in Apparatus for Dyeing or Bleaching Textile Materials. J. Bertrand - Leplat, Tourcoing, France. Eng. Pat. 11,692, July 9, 1891. 8d.

A RECTANGULAR tube, closed at one end and connected at the other with a rotary pump, is fixed horizontally at the bottom of a vat. The tube is perforated at intervals for the reception of a number of tapering socket tubes which project from the bottoms of dye-boxes, in which the material (more particularly cotton sliver) to be bleached, &c., is placed. These boxes are divided into compartments and perforated to admit the liquor. When the pump is set in motion, the liquor passes through the mass of material to the pump, returning thence to the vat, to circulate again through the material. Two sheets of drawings accompany the original specification.—E. B.

Process for Printing and Dyeing Textiles, Fibres, Hair, Feathers, and the Like by Means of Metal Salts. E. Odenheimer, Stuttgart, Germany. Eng. Pat. 17,887, October 19, 1891. 4d.

TEXTILE fabrics, &c. are impregnated with solutions of the salts of gold, silver, copper, iron, uranium, or chromium, and subjected to pressure between heated cylinders or plates. In the case of certain of these salts the effect may be varied by immersing the material to be coloured in a solution of a reducing agent, or exposing it to the action of reducing gases, such as hydrogen and hydrogen phosphide, prior to pressing or calendering. The materials thus operated upon are coloured by the deposition on the same of metallic oxides, basic salts, or finely-divided metals. From sodium "aurochlorate," for example, according to the process employed and the nature and concentration of the reducing solutions, there are obtained perfectly fast shades of grey, purple, red, bronze, and gold.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Specific Gravity of Solutions of Acetic Acid. E. Nickel. Chem. Zeit. 1891, 15, 1793.

THE specific gravity of solutions of acetic acid in water at 15°, rises gradually until a maximum gravity of 1.0748 is reached with solutions of about 80 per cent., after which point, with increasing strength of solution, the gravity falls again until it reaches 1.0553, the anhydrous acid having the same gravity as a 43 per cent. solution. Therefore, taken as an indication of the strength of a solution, any gravity below 1.0552 can only represent one strength, but above 1.0552 the gravity would be that of two strengths; for example, with a gravity of 1.0674 the strength may be either 94 or 58 per cent., a point which is decided by adding water. A rise of gravity would then indicate the higher percentage, whilst a fall would indicate the weaker solution.

PATENTS.

An Improved Method of Enriching Phosphated Chalk and other Calcareous Phosphates. L. C. Delahaye, Paris, France. Eng. Pat. 18,899, November 21, 1890. 6d.

THE phosphatic material is furnaceed in order to transform the calcium carbonate it contains into caustic lime. It is then slaked with water and digested with a solution of

ammonium chloride or nitrate which dissolves out the free lime, and thereby concentrates the phosphatic residue, which is collected on a filter. The solution containing a soluble calcium salt and free ammonia is regenerated for use again by passing a stream of carbonic acid, when calcium carbonate is precipitated and the original ammoniacal salt again formed.

The inventor also claims "the substitution for the ammonia of any kind of ammonia compounds, such as methylamines, ethylamines, whatever be their formula and constitution."—G. H. B.

Improvements in the Production of Chlorine and of Strong Hydrochloric Acid. F. M. Lyte and O. J. Steinhart, London. Eng. Pat. 21,225, December 30, 1890. 8d.

THIS invention is for the purpose of producing chlorine from waste liquors containing calcium or magnesium chloride, and is based on the fact that chlorine and hydrochloric acid are evolved when magnesium chloride is heated in admixture with a suitable magnesite such as Weldon mud, and the yield of chlorine is considerably increased in the presence of substances capable of retarding the giving off of the moisture present under the action of heat. The general reaction is expressed in the equation—

In the presence of sufficient moisture the evolution of chlorine is completed during the heating from 150° to 350° C. The hydrochloric acid evolved in the reaction is separated from the chlorine by condensation and is used in one or other of the various operations so as to be converted ultimately into chlorine only. The invention comprises a series of operations of which the final products are calcium carbonate and chlorine. Calcium chloride is decomposed by treatment with magnesia and carbonic acid. The specification is accompanied by a graphic representation of the interdependent reactions comprised in the process, and this diagram should be consulted in order to follow the cycle of operations. A feature of the process is the low degree of temperature used by which the magnesia is obtained in a "soft burnt" condition, which facilitates the reactions.

—G. H. B.

Improvements in the Manufacture of Sulphate of Alumina. J. W. Kynaston, Liverpool. Eng. Pat. 962, January 20, 1891. 6d.

SULPHATE of alumina, after having been treated for the removal of iron and other impurities, has generally a yellow or greenish colour which is due to the presence of a minute quantity of chromium. This invention has for its object the removal or rather neutralisation of the colour by the addition of a complimentary one. Methyl orange and Tropaeolin OO are suitable colouring matters. The sulphate of alumina solution is concentrated to the required strength, and to the hot solution is added as much dilute solution of Methyl-orange as an experiment has shown to be necessary. The quality of the colouring matter varies, and one part of Methyl orange will produce a neutral grey tint with 600 to 1,200 parts of dissolved oxide of chromium. If the chromium be present as chromic acid it must be first reduced to a chromic salt by means of an alkaline sulphite or other reducing agent.—G. H. B.

An Improvement in the Process for the Simultaneous Production of Cellulose and Oxalic Acid from Vegetable Fibrous Substances. J. Läfschütz, Grünau, Germany. Eng. Pat. 1824, January 31, 1891. 6d.

See under XIX., page 176.

Improvements in Apparatus for the Automatic Control of Sulphuric Acid Supply to Carbonic Acid Generators Used in Aerated Water Manufacture and other Industries. H. C. Cox, Olton. Eng. Pat. 17,034, October 7, 1891. 6d.

THE supply of acid to the generator is regulated by the agency of a syphon with equal arms and turned-up ends which remains filled with acid when lifted out of the liquid. It hangs in suspension over the acid reservoir attached to the arm of a lever which is actuated by the movement of the gasholder. When the gasholder is being emptied the syphon sinks into the acid and delivers a stream of acid into the generator, but when the gasholder is full the syphon is raised from the acid and the flow of acid stops.—G. H. B.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Dark Brown Glaze for Roofing Tiles. E. Cramer. Thonind. Zeit. 1891, 15, 693.

It is advisable to glaze only well-burnt non-porous tiles, as otherwise water finding its way between the joints and at the unglazed edges, and afterwards freezing, will cause the glaze to crack off. A good dark-brown glaze which flows readily has the following composition per cent.: silica, 58.8; alumina, 8.15; ferric oxide, 7.98; lime, 936; alkalis, 6.30; loss on ignition, 8.39; corresponding to the formula—

A loam rich in lime and ferric oxide is best fitted for the production of a glaze of this description; it should be applied to the ware (the latter being in the air-dried condition) suspended in water.—B. B.

The Preparation of Gold Glaze for Stoneware. H. Hecht. Thonind. Zeit. 1891, 15, 694.

GOLD glazes made with purple of Cassius are not always satisfactory, as it is difficult to obtain a uniform admixture of the gold with the glaze by mechanical means. A process has been worked out by Müller, of Brunswick, which depends on the reduction of gold chloride by means of glucose in alkaline solution, which the author has found to give beautiful purple precipitates with such bodies as magnesia, lime, baryta, silica, and alumina. As applied to glazes, the process is carried out as follows:—A dilute solution of gold chloride is mixed with the liquid glaze, the mixture made alkaline with a few drops of sodium carbonate, and slightly warmed while being stirred with a glass rod. The addition of a small quantity of a solution of glucose colours the whole mass bright red after a few minutes. Leadless glazes gave the best results. For example, the following mixture was prepared:—

	Grms.
0.25 K ₂ O	31.50 calcined potash.
0.25 Na ₂ O	95.50 crystallised borax.
0.25 CaO	25.00 marble or chalk.
0.25 BaO	39.25 witherite.
	144.00 sand or quartz.
	12.40 boric anhydride.

80 grms. of this were mixed with 20 grms. of Zettlitzer kaolin and made into a "slip" and treated as described above. Glazes containing 0.01 per cent. of gold were a delicate rose colour after burning, while those containing 0.1 per cent. of gold were dark red, and a mixture with 0.0033 per cent. of gold, together with a little uranium, was yellowish-pink. The use of ammonia instead of sodium carbonate gives dirty bluish-red tones. The brilliancy of the glazes is very great.—B. B.

Change in Porcelain Paste by Storage. H. Seger. Thonind. Zeit. 1891, 15, 813.

WHEN stiff porcelain paste is rendered slightly alkaline with a few drops of sodium hydroxide, carbonate, or silicate, it becomes much thinner, a greater part of the agglutinating material is quickly precipitated and settles firmly at the bottom, whilst the supernatant liquid takes an extraordinarily long time to become clear. If, on the other hand, the porcelain paste is slightly acidified with hydrochloric or acetic acid, it gets so much stiffer that it does not fall out when the containing vessel is inverted. The author suggests that the improvement observed in porcelain paste by keeping may be due to similar molecular changes—probably to acid fermentation of organic matter in the water used—and he therefore proposes to obviate the necessity of long storage by slightly acidifying the paste.—D. A. L.

On a Colour Test of Kaolin and Sand. E. Nickel. Chem. Zeit. 1891, 15, 1125—1126.

THE presence of ferric oxide in kaolin, porous tiles, earthenware, sand, &c. may be demonstrated by the application of a solution of potassium ferrocyanide acidified with hydrochloric acid, the substance so treated becoming instantly coloured blue, of an intensity corresponding with the amount of iron present.

As the test solution soon decomposes, it must be prepared immediately before use. Care must be taken in preparing it that a precipitate of ferrocyanic acid is not produced.

—E. B.

Asbestos Porcelain (Porcelaine d'amiante). M. F. Garros. Compt. Rend. 1891, 113, 864—865.

THIS new material is employed for the filtration and sterilisation of water, wines, vinegar, and other liquids. It is prepared from the purer varieties of asbestos, the fibres of which are among the finest occurring in nature, whether in the animal, vegetable, or mineral kingdom. These fibres reduced to powder yield particles of extreme fineness, and on account of the chemical purity in which the mineral is often found, foreign particles of larger size are entirely absent. If the powder is not absolutely white but coloured with a yellowish tint it is washed with dilute acid to remove the oxide of iron. The powder forms a paste with water which can be moulded to any desired form. The articles are then dried very slowly by gentle heat, and subsequently fired for 17 or 18 hours at a temperature reaching 1,200° C.

The extreme fineness of the pores of this new species of porcelain is shown by the fact that micro-organisms will only penetrate the material to a certain depth, and are not able to traverse the substance as they do in the case of ordinary porcelain. Hence the use of the new material for sterilisation. Water containing 1,200 colonies per cubic centimetre was found to be absolutely sterilised after filtration. After being used for filtration, even for a prolonged period, the asbestos porcelain is restored to its original condition by wiping with a sponge moistened with hot water.—V. C.

Improvements in Couplings for Glass Tubes or for Tubes lined with Glass. D. Rylands, Stairfoot, and R. Morant, Barnsley. Eng. Pat. 3172, February 21, 1891. 6d.

THE invention consists of a socket union made in two parts, the object achieved being the joining up of two tubes by turning either part of the socket instead of turning the

tubes, as when an ordinary sleeve socket is used. The tail part of the socket is furnished with a flange, the head part being provided with a circular chamber, large enough to admit the flange. A washer of gutta-percha coated with shellac renders the joint air-tight.—V. C.

An Improved Tool for Cutting Glass Tubes. A. W. Chesterton, Boston, U.S.A. Eng. Pat. 20,211, November 20, 1891. 6d.

In this tool there are two "spring tensioned arms," provided with a rotating cutter, and with a cutter block

TOOL FOR CUTTING GLASS TUBES.

respectively. There is a fulcrum block between the two arms. One arm is spaced out to measure the length of the tube. A clamping lever encircles both arms, and by changing its position the pressure on the cutting disc can be adjusted.—V. C.

Improvements in the Method of and Apparatus for Manufacturing Plate Glass. W. P. Thompson, Liverpool. From R. S. Pease, Minneapolis, U.S.A. Eng. Pat. 20,437, November 24, 1891. 8d.

In former attempts to improve the manufacture of plate glass, and to make the melting continuous, the plan has sometimes been tried of tipping the whole tank. This involves very costly appliances. Another plan has been to let the glass flow from an opening in the bottom or wall of the tank. The hole, however, becomes rapidly enlarged, and the flow cannot be properly regulated.

The present invention consists in special forms of oven, doors, pots, and so forth, all designed for the purpose of enabling the molten "metal" to be poured straight from the furnace on to the table. The pots, which are somewhat cut away on one side to facilitate tipping, stand in two rows on either side the centre of the furnace, the floor of which slopes so as to form a sort of trough, the bottom of which is closed by doors or gates of fire-brick, backed with iron. The best arrangement is to have one door for each pair of pots. This prevents waste of heat. The floor of the oven or chamber is mounted upon iron beams or girders carried upon columns, leaving a space below the chamber for the casting table, which is of the usual form. The table top is close below the floor of the oven. When the doors or gates are opened and the pots tipped, the metal flows out from the lip of a pot which is itself at a uniform high

temperature through an atmosphere of the same temperature. It encounters no cold body, as is the ordinary method, and consequently arrives on the table in a better condition. Furthermore, the life of the pot is greatly prolonged by this invention, since the alternate heating and cooling is avoided.—V. C.

New or Improved Method of and Apparatus for the Manufacture of Glass Plates, Cylinders, Pipes, and certain other Bodies. W. P. Thompson, Liverpool. From R. S. Pease, Minneapolis, U.S.A. Eng. Pat. 20,439, November 24, 1891. 8d.

It has formerly been proposed to produce a sheet of glass by dipping an iron bar into the molten metal and then raising the bar. Owing to the very different coefficients of expansion of iron and glass, the glass was apt to crack before it could be severed from the iron "bait."

In the present invention a glass "bait" is used, a plunger being allowed to descend until the lower edge of the "bait" dips so far into the molten metal as to cause a partial fusion of the edge. On reversing the motion of the plunger the molten metal follows the "bait." Sheets, hollow cylinders, or other hollow bodies are thus formed. The molten metal must be of the proper consistency, and not too fluid when the "bait" is introduced, otherwise the sheet is too thin. In order to regulate the thickness and maintain uniformity of the glass, the "bait" (which may have, for instance, the form of a hollow cylinder) is cooled inside by a spray of water and outside by a current of air. These arrangements secure a prompt cooling and hardening which enable the thickness to be nicely regulated.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

The Manufacture and Properties of Slag Cement. G. R. Redgrave. Proc. Inst. Civil Eng., Session 1890—91, 105.

THE manufacture of slag cement (for details of which see this Journal, 1890, 863) can only be satisfactorily carried out when the composition and general character of the slag proposed to be used are accurately known. The following table shows the chief constituents of various blast-furnace slags, some well suited, and others wholly unsuited for the manufacture of cement:—

	Silica.	Alumina.	Iron.	Foreign Matter.
South Wales.....	42·84	28·84	23·13	2·11
Lancashire	37·49	10·12	45·97	8·54
Staffordshire	49·05	10·84	34·33	5·78
Scottish.....	32·10	24·28	35·43	8·10
Derbyshire	39·24	23·04	32·05	5·66
North Wales.....	31·28	12·41	46·10	10·21
Cleveland.....	32·15	17·53	45·50	4·82
Cleveland.....	35·45	21·55	33·70	9·30

The cement is made by pulverising granulated slag together with slaked "fat" lime (see this Journal, 1890, 863). In the following analyses the composition of a typical slag cement is contrasted with that of a typical Portland cement.

	Slag Cement.	Portland.
Lime	46.53	60.50
Silica	21.10	22.23
Alumina	16.30	7.22
Oxide of iron	0.93	4.32
Magnesia	2.08	1.10
Carbonic acid.....	0.65	0.80
Water (combined with lime)....	6.45	1.05
Sulphuric acid.....	2.05	1.68
Insoluble and other matters	0.94	1.01
	100.03	100.01

The chemical composition of a slag will not by itself serve to gauge its suitability for making cement, as is shown by the following two examples of slags of very similar composition, one of which had double the tensile strength of the other.

	A.	B.
Silica	21.10	21.22
Alumina.....	16.30	15.61
Lime	47.53	47.19
Oxide of iron	0.93	0.78
Soda, potash, &c.....	5.04	5.56
Carbonic acid.....	0.65	0.85
Moisture.....	6.45	6.88
Total	100.00	100.00

TENSILE STRENGTH—1 CEMENT TO 3 SAND.

A.		B.	
7 Days.	28 Days.	7 Days.	28 Days.
Lb. per Sq. In. 526	Lb. per Sq. In. 431	Lb. per Sq. In. 159	Lb. per Sq. In. 208

Slag cement has a tangible advantage over Portland cement inasmuch as it cannot from its mode of manufacture contain free lime, and therefore does not require "cooling" or aeration. In spite of the fact that it contains about 25 per cent. of slaked lime it keeps well in sacks, a sample thus kept for 15 months only showing a loss of tensile strength of about 5 per cent. When tested to determine its power of resisting attrition by the method used in Germany (this Journal, 1891, 165), slag cement does not give such good results when used neat as Portland cement, but is equal to the latter when a sand mixture is employed. The author considers that the property possessed by slag cement of giving higher results than Portland cement when mixed with large quantities of sand gives this material a value which has hitherto been somewhat overlooked in this country. The following are the results given by sundry slags from different ironworks:—

	1 Part Cement, 3 Parts Sand.		Neat.	
	7 Days.	28 Days.	7 Days.	28 Days.
	Lb. per Sq. In. 396	Lb. per Sq. In. 350	Lb. per Sq. In. 582	Lb. per Sq. In. 698
South Wales.....				
Lancashire	80	120
Staffordshire.....	117	180	230	250
North Wales.....	103	137	285	315
Scotland	227	340	340	415
Cleveland.....	280	398	415	507

The samples had approximately the same fineness, a residue of 10–15 per cent. being left on a 180 × 180 mesh sieve. The briquettes were hardened for 24 hours in air, and the rest of the time in water.

A sample was tested at the Government testing station at Berlin with the following results:—A residue of 14 per cent. was left on a sieve with 5,000 meshes per sq. cm. and of 5 per cent. on one with 900 meshes. All but 1 per cent. went through a 600-mesh sieve. The strength in tension and compression of the sample tested neat and with sand are given below:—

	Tensile Strength after		Compressive Strength after	
	7 Days.	28 Days.	7 Days.	28 Days.
Cement.....	647.0	692.0
Cement to sand = 1:3.	427.0	549.0	337.6	426.9

The results are the mean of a number of concordant tests, and are given in pounds per square inch.—B. B.

Hydraulic Cements. A. Busch. Dingl. Polyt. J. 1891, 232, 116–120.

The difference in tensile strength caused by measuring the quantity of sand and cement used in making standard briquettes by volume instead of by weight has been investigated at the Berlin testing station with the following result:—

		Strength in tension at 28 Days.	Strength in compression at 28 Days.
		Kilos. per sq. cm.	Kilos. per sq. cm.
Slag cement (1)....	By weight..	18.65	131.9
	By volume..	11.25	66.1
Slag cement (2)....	By weight..	22.90	237.4
	By volume..	15.65	161.7
Slag cement (3)....	By weight..	21.60	184.8
	By volume..	12.90	82.2
Portland cement (4)	By weight..	20.90	200.3
	By volume..	19.20	183.0
Portland cement (5)	By weight..	19.96	188.8
	By volume..	17.05	151.6
Portland cement (6)	By weight..	19.39	189.0
	By volume..	18.05	174.9
Roman cement (7)	By weight..	8.55	62.5
	By volume..	3.80	22.6

The briquettes were composed of one part of cement to three of normal sand by volume or by weight as given above, and were allowed to harden under water for the period mentioned in the table.

As might be expected from the comparative lightness of slag and Roman cement, the differences observed were greater in their case than in that of Portland cement, being about 40–60 per cent. as compared with 12 per cent. All the samples were finely ground and of normal specific gravity.

The lengthy time necessary for ascertaining the degree of soundness of hydraulic cements and the uncertainty of the judgments that can be pronounced upon them by the methods in common use, have lead to the device of more expeditious and reliable processes. Prominent among these is that of Deval (this Journal, 1891, 255).

The author has carried out some experiments upon the action of solutions of various sorts upon slag cement. The results are shown in the following table:—

Cement Composed of	Solution Containing	Behaviour after Seven Days.
Blast-furnace slag from Tees Bridge Iron Works, 75 per cent.	MgSO ₄ 1 per cent. + NaCl 1 per cent.	Test pieces "blown."
	NaCl 2 per cent.	Test pieces sound.
Slaked lime, 25 per cent.	MgSO ₄ 2 per cent.	Test pieces disintegrated.
	Sea water.	Test pieces sound.
Blast-furnace slag from Wilson and Pease, 75 per cent.	NaCl 2 per cent.	Test pieces sound.
	MgSO ₄ 2 per cent.	Test pieces disintegrated.
Slaked lime, 25 per cent.	NaCl 1 per cent. + MgSO ₄ 2 per cent.	Test pieces "blown."
	Sea water.	Test pieces sound.

The samples when hardened under fresh water behaved normally. After three months, the test pieces which had been hardened in all the solutions other than that of sodium chloride showed symptoms of failure, the corners being detachable with the finger nail. From these results it appears that magnesium sulphate has an active destructive effect upon slag cement. The author considers it debatable whether this action is due to the fact that magnesium sulphate is a salt of magnesium or to the circumstance that it is a sulphate, and adduces in favour of the former view the well known reaction of lime upon magnesium salts. Against this is the statement of Michaelis, who considers that solutions of calcium sulphate have the same effect as those of magnesium sulphate, while magnesium chloride has no such deleterious influence. He also believes that calcium sulphate combines with free lime to form a basic sulphate Ca_2SO_3 , the existence of which is confirmed by Schott. Whichever be the precise cause, it would appear from these data that slag cement cannot be relied upon for marine work.

The suitability of Sorel's magnesia cement for marine work and its general capabilities have been studied by Weber.—B. B.

Prevention of the Action of Frost on Portland Cement Concrete. Thonind. Zeit. 1891, 15, 754.

REINHOFER recommends the following mixture for concrete to resist the exfoliating action of exposure to very low temperatures:—one litre of Portland cement, one litre of lime and three litres of clean river sand are mixed with a solution of one kilo. of carbonate of soda in three litres of water. The test pieces were exposed to a temperature of about -31.5°C . for $14\frac{1}{2}$ hours and were afterwards heated for three hours without showing signs of injury. (Compare this Journal, 1890, 511.)—B. B.

Artificial Asphalt. E. Valenta. Cent. Org. f. Waarenkunde Tech. 1891, 1, 19; Chem. Zeit. Rep. 1891, 15, 211.

PATENTS.

Method of Manufacturing Artificial Granite and Marble. C. George and C. Wernaer, Berlin, Germany. Eng. Pat. 20,948, December 23, 1890. 4d.

ONE to five parts of finely-ground blast-furnace slag are mixed with 10 to 15 parts of "argilliferous building sand," one part of granite or marble in small pieces, one part of fossil meal, "and a flux of from 3 to 6 per cent. of fluor-spar." A further addition of 3 to 6 per cent. of silicic acid is made if the granite or marble be very fine. The mixture is fused and mixed with a quantity of slag and sand also fused, and is coloured "by the addition of any suitable colouring matter." Small pieces of granite marble, &c. may be added so that they remain partially fused.—B. B.

An Improvement in Building Cements. F. J. Reynolds, Longport, and J. Brown, Hampstead. Eng. Pat. 12,429, July 22, 1891. 6d.

ONE quarter of a pound of pearlsh is dissolved in one gallon of water and freshly-burnt lime slaked with the solution. The slaked lime may be dried, if intended to be kept before being used in the manner described below. A mixture of equal quantities of nitrate of soda and pearlsh may be used instead of the pearlsh alone. The prepared lime is made into the stiffest possible paste with water and 0.5 per cent. of its weight of raw sugar or other saccharine matter added, together with sand, brickdust, blast-furnace slag or similar gritty materials. The mixture may be coloured with various metallic oxides, or salts such as black oxide of manganese or sulphate of copper. It is claimed that the use of the solutions of potash and of nitrate of soda is to effect a finer division of the lime, especially in the case of poor samples.—B. B.

An Improved Fireproof Material. C. H. Köpke, Hamburg, Germany. Eng. Pat. 13,491, August 10, 1891. 4d.

THE patent relates to the utilisation of "the waste products resulting from the manufacture of photogen (light hydrocarbon oils), the coke of bog-head coal, for the purpose of producing a valuable fireproof cement and other fireproof substances." The coke is first calcined, then ground either wet or dry, and moulded into the desired shape. The prepared coke may be used as a cement, alone or mixed with lime or gypsum, or may be mixed with cork, quartz, water-glass and other substances for the production of fireproof materials.—B. B.

X.—METALLURGY.

The Manufacture and Properties of Slag Cement. G. R. Redgrave. Proc. Inst. Civil Eng., Session 1890—1891, 105.

See under IX., pages 163–164.

Note on the Precipitation of Copper by Iron, and the Action of Metallic Iron on Solutions of the Salts of the Sesquioxide of Iron. J. C. Essner. Bull. Soc. Chim. 1891, 3, 147–148.

THE cinders of cupreous pyrites having been alternately moistened and dried by air, when extracted with water

gives a solution of sulphate of copper and salts of the sesquioxide of iron. This treated with metallic iron at 70–80° C. gives metallic copper mixed with a large quantity of the hydrate of the sesquioxide of iron. The copper exists in three forms: powder, grains, and fibres, the form depending on the structure of the iron employed. The cupreous solution contains a basic sulphate of the sesquioxide of iron which reacts with the metallic iron according to the equation—

In solutions of the normal sulphate of the sesquioxide part of the salt is reduced by the iron to the salt of the protoxide $2 \text{Fe}_2(\text{SO}_4)_3 + \text{Fe} = 6 \text{FeSO}_4$. In order to avoid the precipitation of the sesquioxide the cupreous solution was made acid with H_2SO_4 , and this when treated with iron gave a clean deposit of metallic copper.—J. C. C.

On the Determination of the Constants and the Coefficient of Elasticity of Nickel-Steel. E. Mercadier. *Compt. Rend.* 1891, 113, 33–36.

In 1887 and 1888 the author pointed out a method (founded on Kirchhoff's theory of vibration of circular discs) by which it was possible to determine the ratio $\frac{\lambda}{\mu}$ of Lamé's constants

for any sonorous body, and, consequently, the value of its coefficient of dynamic elasticity. The application of this method to various specimens of commercial steel showed that only slight variations existed between them in respect of their elastic properties (using the word in its usual sense as referring to vibratory motions without permanent

deformation). The ratio $\frac{\lambda}{\mu}$ of their constants varied only about 5 per cent. above or below the mean value, and their coefficient of dynamic elasticity varied barely 1 per cent. from its mean value (20,700 at 15°). The ratio of the coefficients of dynamic and static elasticity for these specimens was about 1.035. They contained, however, less than 1 per cent. of foreign substances (carbon, silicon, phosphorus, sulphur, and manganese).

Alloys of steel with chromium and nickel are now used for industrial purposes, and the proportion of nickel in these is sometimes as high as 25 per cent. The author has examined the elastic properties of specimens of nickel-steel from Crenson, the specimens being in the form of circular discs which were reheated to a red heat after being cast. Nos. 1 and 2 contained 5.55 per cent. of nickel; Nos. 3 and 4, 25.01 per cent. Discs 1 and 2 (although from the same melt) did not show the same degree of

homogeneity, for the ratio $\frac{\lambda}{\mu}$ had the value 2.29 for the first, and 1.60 for the second; the discs were far from being isotropic. On the other hand their coefficients of dynamic elasticity only differed by 2 per cent. from the mean value (19,922). The discs 3 and 4 were almost isotropic, their values for $\frac{\lambda}{\mu}$ being nearly equal to unity.

This remarkable result appears to indicate that the incorporation of nickel (in sufficient quantity) with steel tends to make it isotropic. At the same time it produces a considerable variation in the coefficient of dynamic elasticity, reducing it (for 3 and 4) to 18,600, whereas that of pure steel is 20,700 (a variation of 10 per cent.).

The ratio of the coefficients of dynamic and static elasticity is 1.035 for pure steel, 1.17 for steel containing 5.55 per cent. of nickel, and 1.51 for steel containing 25 per cent. of nickel. Tests of the latter made in the manufactory by the ordinary statical methods gave values of the coefficient varying from 12,000 to 6,000 according to the size of the specimen and the mode of treatment; the specimens yielded such very different results that under the circumstances it was impossible to regard the coefficient of static elasticity as having any real and determinate significance.

—D. E. J.

Refractory Bricks of Magnesite and Chrome Iron Ore.
Leo. Thonind. *Zeit.* 1891, 15, 700.

THE author ignited a sample of magnochromite from Tampadel in a Deville blast furnace to ascertain its capability of withstanding the temperature of an ordinary open-hearth steel furnace. The sample had the composition:—chromic oxide, 35–42 per cent.; ferric oxide and alumina, 19–22 per cent.; magnesite, 16–18 per cent.; and silica, 3–5 per cent. The lining of the Deville furnace was of magnesite, and a magnesite brick and a Dinas fire-brick were heated at the same time for the sake of comparison. The result of the experiment shows that the chrome iron ore and the Dinas brick were completely fused, while the magnesite lining and the magnesite brick were unaffected by the heat and unattacked by the fused sample.

—B. B.

Action of Sulphuric Acid and Nitric Acid on Aluminium.
G. A. Le Roy. *Bull. Soc. Ind. de Rouen*, 1891, 19 232.

THE author states that the commonly received view that aluminium is unattacked by sulphuric acid or nitric acid whether concentrated or, dilute is erroneous. Four samples of aluminium were examined by him, they had the following composition:—

	Aluminium.	Iron.	Silicon.
	Per Cent.		
A.	98.28	1.60	0.12
B.	98.45	1.39	0.25
C.	99.60	0.30	0.10
D.	99.47	0.43	0.13

The samples which were in the form of sheet were freed from traces of grease by means of caustic soda, washed with alcohol, dried and weighed and exposed to the action of acids of various strengths for 12 hours. The results which are given below correspond to the weight of the metal dissolved, calculated in grms. per square metre:—

Kind of Acid.	Sp. Gr.	Temp.	A.	B.	C.	D.
		° C.				
Pure sulphuric.....	1.842	..	18.40	18.10	16.40	14.50

Commercial sulphuric	1.711	..	25.80	24.70	21.60	22.40
Pure sulphuric.....	1.580	15–20	19.00	18.00	17.90	16.30
Pure sulphuric.....	1.263	..	4.60	..	2.60	3.40
Pure nitric	1.383	..	17.00	16.00	15.50	14.50
Commercial nitric ...	1.383	..	20.50	19.60	18.00	16.60
Commercial nitric ...	1.382	..	16.30	16.50	14.00	13.40
Pure sulphuric.....	1.842	150	240	225	150	200
Commercial sulphuric	1.842	150	267	250	210	220
Pure nitric	1.383	100
Commercial nitric ...	1.383	100

From these figures it is apparent that even commercially pure aluminium is attacked in the cold by both nitric and sulphuric acids of whatever quality, and that, therefore, its proposed use for vessels for the preparation of these acids is ill-advised.—B. B.

The Manufacture of Cobalt. United States Consular Reports, September 1891.

THE large and important chemical works of the Maletra Company, at Rouen, finding that the manufacture of soda and its products had ceased to be profitable, determined to seek some better use for the large portion of their factory which had been used for this purpose. In searching for a substitute which would employ the workmen, utilise the machinery and buildings, and employ the capital and afford profit, the direction naturally sought for some production for which France relied upon other countries for its supply. They found that cobalt was almost a monopoly confined to four or five English and German houses, although the mineral is almost entirely brought from New Caledonia, which is a French colony.

The cobalt for trial was bought in the London market and experimented upon in the well equipped laboratories of their works. The results were conclusive. No doubt existed that this new departure was perfectly practicable. The only difficulty was to obtain the raw material.

The mineral cobalt abounds in New Caledonia and is inexhaustible and co-extensive with the island.

The working of the mines of the mineral is easy, as it is often found on the surface, and when it is below the trench does not exceed 20 ft. in depth. The cost is very little, and it requires to be, for the mineral contains only about 2 per cent. of cobalt.

The veins of cobalt are irregular impregnations of asbolane disseminated through large masses of clay tinted with iron.

This asbolane is found in several states. It is easily cut with a knife, and the section is of a characteristic blue-black lustre. It is mixed generally with silica, oxide of iron, and clay. Although the mineral varies in the different mines, the following analysis gives an approximate idea of its composition:—

Components.	Per Cent.	Components.	Per Cent.
Peroxide of manganese	18	Lime	1
Protoxide of cobalt ..	3	Magnesia	1
Protoxide of nickel ..	1.25	Lost by drying (water and oxygen in excess)	32.75
Silica	8	Total	100
Peroxide of iron ...	30		
Alumina	5		

The mineral thus obtained is sent directly to the London market, on account of the facilities of transportation afforded by English vessels. These ships, carrying wool from Australia, find it very convenient and profitable to take in for ballast the mineral cobalt, which enables them to carry more wool, as the fibres of the wool, like those of cotton, are liable to be broken under pressure. The freight of the mineral to London is about 15 to 18 francs per ton.

The London market has thus become the only centre of supply. In purchasing this article at London the tax imposed of 36 francs on entry into France upon articles from countries outside of Europe brought to European depôts prevented competition in their home market with their English and German rivals. The only remedy was to temporarily admit the mineral upon the express stipulation that the product should be all sold out of France, and thus avoid the payment of duties.

This deprivation of the entire French market interfered with the plans of the company. They undertook to import directly from Nouméa by a maritime transportation company richly subsidised by the French Government. This company offered to carry the freight at first at 28 francs per ton. This was an advance of 10 francs upon the London freight; but having no competition, soon raised their rates to 31 francs, and then to 51 francs, which was prohibitive. In the meantime the Maletra works sent a most competent and experienced metallurgist to New Caledonia. During a residence of 18 months he made a thorough examination, and on his return reported a new process for treating the minerals of cobalt. Soon after he

came back, about three years since, the company installed in the part of their establishment formerly devoted to the manufacture of soda the apparatus for treating the minerals of cobalt.

The following is a description of the method employed by the Maletra Company:—

The mineral in a state of powder is thrown into large vats filled with a solution of protosulphate of iron and thoroughly mixed up by a jet of steam. The manganese, the cobalt, and the nickel are taken up by the liquid in the form of sulphates. The iron that is in the mineral, as well as that in the solution, is precipitated in the form of peroxide and partly as persulphate, with the alumina and silica. The liquid, containing in solution the manganese, cobalt, and nickel, is drawn off, and the residue (containing iron and alumina) is passed through a filter-press and after calcination can be used as colcothar. The protosulphate of iron used in this operation is made in the establishment by attacking scrap iron by one of the residues rich in sulphuric acid known as bisulphate of soda. This bisulphate of soda forms, with the scrap iron, protosulphate of iron and also sulphate of soda, used subsequently. The sulphate of soda is separated by crystallisation. The liquid containing the manganese, cobalt, and nickel is run into stone basins, to which is added sulphide of sodium, which precipitates the whole of the cobalt and nickel, but leaves the greater part of the manganese in solution. The sulphide of sodium is produced in a corner of the establishment by boiling in a closed vessel one of the by-products of their establishment—black-ash waste from their carbonate of soda furnaces—and the sulphate of soda residue from making the protosulphate of iron already described.

The precipitate containing the cobalt, nickel and a small quantity of manganese is washed, passed through the filter-press and then treated with perchloride of iron (produced in one of the succeeding operations), which dissolves the manganese. This second operation gives (1) a black precipitate of comparatively pure sulphides of cobalt and nickel; (2) a liquid containing sulphate and chloride of manganese. To the liquid is added chloride of lime, obtained in one of the subsequent operations, and the manganese precipitated by the lime becomes a by-product used in the Weldon process.

The third operation consists of drying the sulphides of cobalt and nickel and then carefully roasting them in a reverberatory furnace, when, if carefully done, the sulphides become soluble sulphates of the two metals.

The fourth operation is the most difficult and remarkable one. The soluble sulphates are now washed with boiling water. The solution is treated with chloride of calcium. Of the solution (a) containing chloride of cobalt and nickel a certain quantity is taken, and the cobalt and nickel are precipitated by lime. This precipitate of oxide of nickel and cobalt is washed to remove any chloride of calcium that might remain, then placed in a suitable vessel, a sufficient quantity of water added, and submitted to a current of chlorine gas and air under pressure to produce a thorough mixing. To the peroxides so obtained is added a new portion (b) of the liquid a, and the two mixed up thoroughly by a jet of steam, and a curious change takes place. The peroxide of nickel, changing into protoxide, enters into solution and is displaced continuously by an equivalent proportion of cobalt from the first solution. The liquid then contains chloride of nickel, the cobalt being precipitated as peroxide of cobalt. The second portion (b) is calculated so as not to displace the whole of the nickel. This liquid is now run off and a fresh quantity of a added, and so on until on testing it is found that the precipitate contains nothing but peroxide of cobalt pure, when the operation is finished. The solutions containing nickel are treated with lime, and the nickel precipitated as oxide. The products of the operation are (1) protoxide of nickel, (2) peroxide of cobalt, (3) chloride of calcium. The chloride of calcium is required in one of the preceding operations. The separated oxides of nickel and cobalt are filter-pressed, dried and calcined.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Secondary Batteries. G. H. Robertson. Jour. Soc. Arts, 1891, 40, 44—61.

In the introduction the author traces briefly the history of the secondary or reversible battery from its first discovery by Gautherot in 1801, to the discovery of the peroxide of lead—lead couple—by Planté in 1859.

Passing on to 1880, the date of the introduction of the Faure cell, when the growth of electrical engineering led to a commercial demand for some means of storing electrical energy, the copper-zinc, lead-zinc, copper-lead, and alkaline copper forms of secondary cells are shortly described. Then the author deals with the improvements which have been effected in the Planté and Faure types of lead reversible batteries, and points out that since the characteristics of the original cell are common to all, it is important to discover whether they can be affected by mechanical alterations, or whether they are due to the chemical reactions involved in the working of the couple. The first part of the paper deals with the principal improvements in construction.

1. *Improvements in the Planté Type.*—The Planté type is defined as that in which the peroxide of lead and spongy lead are formed direct from metallic lead by electrolysis. In this type obtaining porosity has been the chief aim of inventors, since both the weight of the plate and the time required for formation can be shortened by making the plate porous, and thus exposing more surface to the action of the acid and charging current. The methods which have been suggested from time to time may be classified under three headings:—

A. *Chemical.*—The plates are subjected to some "pickling" process, or some special "forming" bath is used.

B. *Mechanical.*—The plates are made of granulated lead, wire, or some form of finely-divided lead.

C. *Electrolytic.*—(1.) The finely-divided lead is obtained by the electrolysis of some salt of lead; (2.) some salt of lead is formed into a plate by pressure, or otherwise, and then reduced to metallic lead.

II. *Improvements in the Faure Type.*—The Faure type is defined as that in which the peroxide of lead and spongy lead are formed by electrolysis from some oxide applied to the plates.

In this class of cell it is obviously desirable that the supporting part of the electrode should be light and not weakened by taking part in the chemical reactions. These requirements have been met in many instances by replacing the solid lead plate by a grid, usually made of an alloy of lead and antimony, since such an alloy is less acted on by the acid and is much stronger than pure lead.

The other improvements fall into two principal divisions:—

A. Those which have for their object the retention of the paste on the plate, and they may be classed under four headings:—

- (1.) The plate is not perforated, but grooves or recesses are made on the surface so as to afford a lodgment for the active material.
- (2.) The support is some form of "grid."
- (3.) The active material is enclosed in a perforated conducting retaining vessel.
- (4.) The enclosing vessel or plates are made of some non-conducting material, or some inactive substance is packed between the plates to prevent short-circuiting and retain the active material.

B. Those intended to provide better connection between the support and the active material.

Instances under each heading are given from cells and processes of formation in commercial use. The cells described are the "Reynier," "E.P.S.," "Oerlikon," Messrs. Drake and Gorham's "D.P.," "Tommasi," "Julien," "Gadot," "Crompton-Howell," "Atlas," "Roberts,"

"Legay," "Tudor," and all the information which could be obtained in respect to these cells is given in a tabulated form.

In the second part of the paper the author deals with the chemistry of the acid, and points out that although so many different modes of manufacture and preliminary treatment have been resorted to, all the batteries which depend for their action on the couple formed between lead and lead-peroxide in dilute sulphuric acid, exhibit the characteristic peculiarities noticed by Planté in his cell, namely:—The high initial E.M.F. of a freshly-charged cell; the fall of E.M.F. on breaking the charging circuit, with corresponding rise on breaking the discharging circuit; the very rapid fall towards the end of discharge which occurs earlier the more rapid the discharge is, and is not due to the exhaustion of the active material, as after a rest a fresh discharge can be obtained. As the defects, namely, sulphating and buckling, which have retarded the introduction of reversible lead batteries, are also common to the two types, it appeared possible that they were due to the same causes which produced the variations in E.M.F., and which Planté has ascribed to the formation of peroxides in the acid. Berthelot, in 1878, discovered persulphuric acid ($\text{H}_2\text{S}_2\text{O}_8$), and showed that it is the primary product of the electrolysis of sulphuric acid solutions, and that its decomposition is attended with the formation of hydrogen dioxide.

As there was evidence to show that the addition of sodium sulphate, as recommended by Barber Starkey, affected the E.M.F. of the cell, it seemed possible that the different behaviour of cells containing this substance was due to its catalytic action on hydrogen dioxide, and furnished a clue to the reactions normally occurring.

The investigation was aided by Mr. Preece, who allowed experiments to be carried out at the General Post Office, where one half of the secondary cells contain 1 per cent. of sodium sulphate and the other half ordinary dilute acid, density 1.180. The Post Office records showed that the sulphating was much less in the case of cells containing sodium sulphate than in those without. As an instance of this, in the case of two short-circuited cells with badly broken plates, the density of the electrolyte had fallen from 1.170 and 1.180 respectively to 1.100, while in two sodium sulphate cells under similar conditions the density had only fallen from 1.200 to 1.180. This was strong evidence in favour of the hydrogen dioxide formed in the working of the cell being appreciable in quantity, since if sulphating were only due to local action between the support and the paste, there does not appear any reason why the addition of sodium sulphate should affect it.

In the sodium sulphate cells the amount of the oxidising agent was usually less than in the plain cells. Whenever the cells were tested they were always found to contain "active oxygen," which was due to the presence of persulphuric acid and peroxide of hydrogen in varying proportions. It was also found that electrolysed acid was able to reduce pure peroxide of lead in a flask where the reduction could not be due to local action.

The cause of the pink colour of the acid, sometimes noticed, was found to be manganese. This result is important, for it is well known that the pink colour disappears from the acid in a short time if it is taken from the cell, and as persulphuric acid has no action on permanganate, but hydrogen dioxide decolorises it, this disappearance of the colour shows that the latter is formed.

The presence of hydrogen dioxide having been proved, both directly and indirectly, its effect on the E.M.F. of the cell was tested, and it was found to increase the E.M.F. when present at the peroxide plate, but to lower it when present at the lead plate.

In conclusion, the author points out that from the same faults appearing in cells of such different construction, and judging also from the results of the experiments recorded in the paper, it would appear that the troubles occurring in batteries are due rather to causes arising in the working than in the manufacture. What is required is some substance which can be added to the acid to check the formation of the oxidised bodies in it, which cause sulphating, without at the same time injuring the plates in other ways.

In discussion, Mr. James Swinburne said that he had tried a number of experiments on forming processes, and thought the best results were obtained by the use of a solution which first dissolved the lead and then precipitated it. Nitric, sulphuric, and acetic acids, various chlorides, and a large number of other solutions were tried, but the great trouble was that traces of the material were left in the cell which would eventually eat through the plate and destroy it. The least trace of chloride was fatal. The best results were obtained with a mixture of acetic and sulphuric acids. By increasing the strength of the acid a higher E.M.F. could be got, but there was a limit to the strength which could be used, as at a certain strength the spongy lead began to decompose the solution. He regretted more information had not been given about copper and other cells, and believed the tendency now was to turn to copper for the cell of the future.

Mr. M. Immisch said the cells now made would be very satisfactory if manufacturers would give them more output in proportion to their weight. He had tried solid peroxide plates, but though at first the results were marvellous they did not last.

Mr. Bernard Drake said if excessive sulphating could be avoided there would be no buckling; but if batteries were allowed to run out, and were left under conditions which would produce excessive sulphating, nothing would save them. The specific gravity of the acid should be varied according to the work required. With regard to copper cells the return in proportion to weight was certainly greater than from lead, but the invariable difficulty was that the zinc appeared to be soluble in the solution.

Mr. Robertson, in reply, said diminution of weight was, of course, the great point, and he hoped when they knew more about what happened in a cell they would be able to construct them better. Mr. Drake had confirmed his view that the strength of the acid should depend on the work to be done.

The Chairman (Mr. W. H. Preece) thought that the cause of buckling was one of the great troubles chemists ought to attack. He also gave an instance of the practical use of soda. In May last it was reported to him that there were 28 E.P.S. 13 L cells terribly sulphated, which had resisted various attempts to get them into order. About half a pint of a saturated solution of carbonate of soda was added to each cell, and at once the whole difficulty disappeared.—G. H. R.

Artificial Asphalt. E. Valenta. Centr. Org. f. Waarenkunde. Tech. 1891, 1, 19; Chem. Zeit. Rep. 1891, 15, 211.

See under XIII., page 170.

PATENT.

Improvements in the Manufacture of Leclanche Cells. D. Rylands. Stairfoot. Eng. Pat. 3170, February 21, 1891. 6d.

THE object of the invention is to keep the porous pot in the centre of the glass cell, and so that it shall not touch the inside of the mouth of the glass cell. This is accomplished in one of three ways: first, while the bottom of the glass is in a plastic state a plunger is introduced, forming a depression in the thickness of the glass bottom. Into this depression the porous pot fits; or secondly, a shallow glass cell is introduced into such depression, and the porous pot stands inside the shallow glass cell; or, thirdly, the bottom of the glass cell is indented from the outside, and the bottom of the porous pot is indented also from the outside in such a way that the pot fits over the raised portion of the bottom of the glass cell, and is retained in this manner in a vertical position in the middle of the glass cell.—V. C.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

A Rapid Method of Determining the Composition of Lubricating Oils. H. Gripper. Chem. News, 1892, 65, 27—28.

See under XXII., page 182.

PATENTS.

Improvements in the Separation or Treatment of Fatty or Greasy Matters from the Wash-Waters of Wool-Washing or Scouring Establishments. C. W. Kimmins, Cambridge, and T. Craig, Bradford. Eng. Pat. 92, January 2, 1891. 6d.

IN the processes now generally in vogue for separating fatty matters from wash-waters, the sulphuric acid used acts injuriously on the fatty materials as well as on the apparatus used for their mechanical separation. To minimise the objectionable action of the acid the patentees precipitate the fatty matter from wash-waters by means of either suitable neutral salts, such as chloride of calcium or these in conjunction with lime or bleaching powder. From the separated fatty matters a better cake may be obtained by the addition of a small quantity of a soluble sulphate. The cake is decomposed with sulphuric acid, and the colour of the resulting product may be improved by passing through it air, gas, or steam, at a comparative low temperature.

—K. E. M.

Improved Filter for Oils, Lubricants, and other Fluids. W. H. Willeox, London. Eng. Pat. 101, January 2, 1891. 6d.

THIS oil filter consists of two concentric cylinders, the inner cylinder communicating with the annular space, through grids at the bottom, and between which a suitable filtering medium is placed. The oil to be filtered being placed in the annular space between the two cylinders, rises up through the grids and filtering medium into the inner cylinder, whence the filtered oil is removed through a suitable pipe.—O. H.

An Improved Oil Filter. C. E. Masterman and "Woodhouse and Rawson, United Limited," London. Eng. Pat. 1976, February 3, 1891. 8d.

AN air-tight vessel of metal or other suitable substance preferably cylindrical, is divided by a horizontal diaphragm into two chambers, the upper for the reception of dirty oil to be filtered, and the lower for the collection of the clean filtered oil. The diaphragm consists of a disc of perforated metal or wire gauze, upon which is laid fine cotton waste and one or more discs of perforated metal, with corresponding layers of cotton waste, the whole being kept in place by a perforated plate on the top, pressed down by a heavy iron ring. The lower chamber is fitted with an inlet and an outlet cock at the top, and an outlet cock at the bottom, by means of which it may be filled with clean oil to start with, the out-flow of which will tend to aspirate the dirty oil through the filter-plate. A separate vessel may be connected with the upper chamber as a settling tank for the dirty oil, and to allow any water it may contain to separate before passing to the filter.—B. B.

Improvement relating to Candles. G. E. Farrow, London. Eng. Pat. 16,986, October 6, 1891. 6d.

IN order to extinguish candles automatically and at the same time prevent waste, the patentee secures an obstruction of suitable non-combustible material upon the wick. When the candle burns down to the obstruction this will cause extinction. The remaining small piece of candle may now be inverted and relighted by the projecting part of the wick at the lower end.—K. E. M.

An Improved Lubricating Compound for the Chains and Bearings of Cycles and for other Purposes. H. H. Lake, London. From J. Ketchum, Brooklyn, U.S.A. Eng. Pat. 17,553, October 14, 1891. 4d.

METALLIC chromites, preferably chromite of iron, in the condition of an impalpable powder, mixed with glycerin or other suitable "suspending or binding material" is said to be an efficient lubricating compound for bearings of all kinds.—K. E. M.

Improved Method of and Apparatus for Extracting Fatty Particles from Emulsions. C. D. Hellström, Sala, Sweden. Eng. Pat. 17,654, October 15, 1891. 6d.

WITH a view to increase the rapidity and completeness of separation of fats from emulsions such as milk, the patentee makes use of a centrifugal separator in which the emulsion on its passage from the centre to the casing has to take an undulatory path between discs or rings consisting of con-

APPARATUS FOR EXTRACTING FATTY PARTICLES FROM EMULSIONS.

centric corrugations. Annexed Figure shows the arrangement used by patentee.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Pigments and Vehicles of the Old Masters. A. P. Laurie. J. Soc. Arts, 1892, 125, 133, 150—164, and 171—178.

Of the great variety of pigments used by the old masters many are only suitable for miniature painting or under conditions where they are protected from the action of sunlight and moisture. A few only were used in fresco painting. Other pigments which were admissible in the purer air of ancient cities or in dry climates such as that of Italy, are unsuitable in the atmosphere of modern towns and in moister climates. In reviewing the list of the pigments generally employed for oil painting by the old masters one is struck by the fact that many are of such a character as to act injuriously upon other pigments unless carefully isolated. Yet such pigments are frequently found to have preserved their brilliancy for centuries. Others again are affected by air in the presence of moisture. The author shows that the oils and varnishes usually employed at the present time are far from furnishing a perfect protection from the access of air and moisture. In these experiments dehydrated copper sulphate was coated with the varnish, placed in a desiccator and subsequently exposed, when the more or less rapid colouration of the copper sulphate proved the incomplete character of the protection afforded by the varnish. Similar experiments are considered by the author to disprove Eastlake's theory that the preservation of the colour in such

paintings as those of Van Eyck is due to the use of an *oleoresinous* vehicle, i.e., one in which a resin dissolved in oil is mixed with oil. The author is rather inclined to attribute the preservation of these colours to the use of *balsams* such as Venice turpentine (the balsam of the larch) which he finds to afford a fairly complete protection from moisture. He points out, however, that these balsams are unsuited for modern work, owing to their stickiness, which does not admit of rapidity of execution. Much might be done, however, for the permanence of modern paintings by the exclusion of dangerous pigments, the careful preparation of the pigments used, and particularly by paying more attention to the purity and mode of preparation of the oils.

The author deals at some length with the properties of white lead. The old masters appear to have uniformly employed that made by the Dutch process which contains hydrate. The presence of the hydrate results in the formation of a lead soap with the oil, thus forming a leathery substance of great durability. The precipitated white lead preferred by modern artists on account of its greater purity of colour has not this property. A mixture of the two is believed to be fairly satisfactory. The author considers that too much importance is attached to the fact that a sulphurous atmosphere discolours this pigment, as the colour is restored by exposure to sunlight.—V. C.

Artificial Asphalt. E. Valenta. Centr. Org. f. Waarenkunde u. Tech. 1891 1, 19; Chem. Zeit. Rep. 1891, 15, 211.

By adding sulphur to molten rosin a clear mass is obtained which on heating turns brown, froths up and gives off hydrogen sulphide; at 250° this evolution of gas is regular until it ceases, when the mass becomes brownish-black. The product contains sulphur, is pitchy, and closely resembles Syrian asphalt in properties. It is insoluble in alcohol, but dissolves readily in chloroform and benzene; a thin layer of the latter solution when allowed to dry on glass, deposits a solid varnish which is extremely sensitive to light.—D. A. L.

PATENTS.

The Manufacture of an Improved Preparation of Dryers or Siccative Material for Mixing with Paints. W. N. Hartley, Dublin, and W. E. Hlenkinsop, London. Eng. Pat. 1267, January 23, 1891. 4d.

This preparation is a mixture of manganese linoleate with a finely-powdered metallic oxide or salt, which can have no injurious action on the paint, such, for example, as zinc oxide, carbonate or sulphate, china clay, silica, or kieselguhr. The mixing may be made by beating the materials to steam heat and triturating in a mortar or by rubbing with turpentine.

Good results are said to be obtained by using 40 parts by weight of manganese linoleate dissolved in 120 parts of turpentine and afterwards mixing with 1,000 parts of zinc oxide. This powder may be used for mixing with paints. To prepare a liquid dryer an oil containing 1 per cent. manganese linoleate is treated as described in Eng. Pat. 11,629, of 1890 (this Journal, 1891, 263), and prolonged till the oil becomes thickened, when it is diluted with a suitable solution of the linoleate till it contains about 10 per cent. This dryer will then mix completely with oils or oil paints.—D. A. S.

Improved Polishing Composition. H. E. Hickox, London. Eng. Pat. 12,951, July 30, 1891. 4d.

This composition is intended as a substitute for black-lead, and consists of either size, water, plumbago, and ammonia, or of size, vinegar, water, plumbago, camphor and ammonia, in suitable admixture.—D. A. S.

Apparatus for the Manufacture of Lamp-black Carbon-black. E. Binney, New York, U.S.A. Eng. Pat. 17,221, October 9, 1891. By Internat. Conv., March 9, 1891. 8d.

This is an improved method of making lamp-black from oil, and carbon-black from gas, more economically.

The general practice hitherto in making lamp-black has been to draw the oil flame into a special chamber for a time, and subsequently, when the building is cooled, workmen are sent in to scrape down and remove the lamp-black. It is claimed the new process by saving labour is more economical.

Hitherto carbon-black has been made by allowing a gas flame to impinge directly on a metal surface, from which the deposited black is subsequently scraped. This method of manufacture tends to give the carbon-black a granular form on account of the high temperature, and so in the manufacture of ink, in spite of its superior colour, it has to be mixed with lamp-black to give it flaky texture. It is claimed that by this process the product, while retaining the superior colour of carbon-black, has also the soft flaky texture of lamp-black.

The apparatus is simple, and practically consists in the suitable combination of an oil or gas burner or furnace, with a depositing chamber, the walls of which are out of contact with the flame. The chamber has a revolving scraper to remove the black from the walls, and a conveyor to carry it continuously out.—D. A. S.

Improvements in or relating to the Manufacture of Resinous Paint. W. P. Thompson, Liverpool. From A. F. von Pereira, Stuttgart, Germany. Eng. Pat. 18,072, October 21, 1891. 4d.

This preparation consists of a mixture of 325 parts of copaiba balsam, 25 parts of lavender essence, and 15 parts each of mastic and of dammara resin, which can be rubbed up with the desired colours.

It is claimed that when this resinous paint is used the paintings will not become dark, nor their surface crack, nor will their transparency and durability be interfered with, a drawback which has hitherto attended all such resin colours used without the addition of fatty oils.

These colours dry completely in about 24 hours, and are excellent for painting on glass and metal, even when employed by themselves. When used in distemper painting they can be painted on again with distemper if desired.

—D. A. S.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Role of Arsenic in Tanning. S. Sadlon. Der Gerber, 1891, 17, 284.

THE addition of sulphide of arsenic to limes is known to effect a more complete unhairing and to prevent too much plumping of the hides or skins. The condition of the hides from such limes is sounder and of better quality, this improvement manifesting itself in tawed leather by the greater softness and gloss of the grain, and in tanned leather by a better quality of the grain. It has heretofore been accepted that the sulphide of arsenic merely acts in the limes as a carrier of sulphur, converting a portion of the lime into calcium sulphide, the arsenic being itself of no service. The author's observations show that while it is true that the sulphide of arsenic converts a portion of the lime or alkalis into sulphides, the arsenic is by no means unserviceable, for it prevents putrefaction and fermentation, and thus greatly aids the improvement in the leather. Although alkaline sulphides alone will not effect the same improvement as sulphide of arsenic, an addition of common salt, together with an alkaline sulphide, is attended by much the same results as those obtained by the use of sulphide of arsenic.—A. G. B.

PATENT.

A New or Improved Process for Tanning all kinds of Hides or Skins. W. Bolt, Glasgow. Eng. Pat. 3176, February 21, 1891. 4d.

THE inventor mixes with the solution of catechu or other tanning material a solution of chloride of sodium or sulphate of magnesium, or both.—E. J. B.

XV.—MANURES, Etc.

PATENTS.

Improved Method for Precipitating Solid Matter in Sewage, Purifying and Disinfecting the Effluent Water, and Solidifying and Preparing the Sludge for use as a Manure. J. Hardwick and L. A. Newton, London. Eng. Pat. 15,405, September 29, 1890. 6d.

XVII.—BREWING, WINES, SPIRITS, Etc.

On Wine Yeast. A. Rommier. Compt. Rend. 1891, 113, 386—387.

A VINEYARD in the Dordogne was planted with vines of the best kind from the Médoc, grafted on American vines. After three years, a good crop of grapes was obtained which yielded a good wine, but of no different character from wines of that part of the country generally. If, however, before fermentation, uncrushed grapes from the Médoc or fresh must therefrom be added to the must from the grapes above mentioned, a wine is obtained having absolutely the same character as the Médoc wine.—A. L. S.

Iso-maltose in Beer and Wort. C. J. Lintner. Zeits. ges. Brauw. 1891, 14, 281.

LEAD acetate is added to one and a half litres of beer, the filtrate neutralised with soda and concentrated to a syrup. The concentrated solution is poured into one litre of absolute alcohol; the precipitate consists chiefly of dextrin; the clear alcoholic solution is concentrated and again treated with alcohol; a precipitate is thrown out which, with phenylhydrazine acetate, yields a yellow precipitate, and when purified by several recrystallisations forms aggregations of yellow needles which begin to run at 138°—140° C. and finally melt at 150°—153° C. They have the same composition and properties as iso-maltosazone described by Fischer. This body was also obtained from wort.—A. L. S.

The Application of Aluminium for Vessels for containing Foods, &c. G. Rupp. Dingl. Polyt. J. 1891, 283, 19—21.

See under XVIII.—A., pages 172—173.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A).—CHEMISTRY OF FOODS.

The Artificial Colouration of Articles of Food. A. Tschireh. Schweiz. Wochenschr. Pharm. 1891, 29, 344.

THE green colouring matter of leaves is extremely sensitive to light and to acids of all kinds. To prevent its decolourisation, sodium carbonate is commonly added to vegetables before cooking, while preserved vegetables were formerly boiled in copper vessels but are now treated directly with copper sulphate, well washed, sterilised, and soldered down. The author explains the reactions taking place in the following way. By treatment with sodium carbonate the free fatty, and vegetable acids are neutralised, the fats saponified, and acid salts such as potassium binoxalate converted into the neutral compounds. Not only is the action of the vegetable acids upon the chlorophyll, which results in the conversion of the latter into phyllocyanic acid (a brownish-green body), prevented by the addition of alkaline carbonate, but there is formed the sodium salt of the acid in question which is a fairly stable green substance soluble in water and insoluble in ether. The corresponding copper salt which the author has obtained in the form of black plates with a steel blue reflection is, however, still more stable; the copper it contains does not give the usual reactions until the salt has been destroyed by ignition; it is always formed when the green parts of plants are treated with copper sulphate solution; it contains about 9 per cent. of copper. Seeing that the quantity of chlorophyll in such vegetables as are commonly preserved in this manner, as for example, peas and cucumbers, is very small, the amount of copper solution necessary to preserve the colour is correspondingly minute. The author considers that it is impossible to procure preserved vegetables of brilliant colour which have not been coppered, and is disposed to fix a maximum limit for the quantity of copper, believing that the traces usually present are innocuous.—B. B.

Fruit of the Wax Palm (Corypha cerifera L.) as a Coffee Substitute. J. König. Centr. Org. f. Waarenkunde u. Tech. 1891, 1; Chem. Zeit. Rep. 1891, 15, 208.

THE fruit of *Corypha cerifera* is of stony consistency, and in Brazil is made into a substitute for coffee by roasting in the ordinary manner. Chemical analysis of the Brazilian fruit gave the following numbers per cent. :—

	Crude.	Roasted.
Water.....	Per Cent. 9.37	Per Cent. 3.76
Albuminoids.....	5.82	6.14
Fat.....	10.57	11.06
Sugar and dextrin.....	1.67	1.25
Starch.....	2.47	5.46
Other non-nitrogenous extract substances.....	23.01	27.79
Woody fibre.....	41.31	38.45
Ash.....	2.06	2.24
Ash containing :—		
potash.....	0.63	0.69
lime.....	0.12	0.45
phosphoric acid.....	0.41	0.43
Substances soluble in water.....	12.17	13.50

The fat from the fruit differs in composition from that obtained from the leaves.—D. A. L.

The Adulteration of Foods in Various Countries. Rev. Inter. des falsificat. 1891, 4.

Milk.—Of 214 samples of London milk 44 had been deprived of their cream, boracic acid had been added to 21, and 26 were poor; 6 had an abnormal composition containing 6.7—14.25 per cent. of fat. Of 959 samples of Amsterdam milk 13.7 per cent. were unsatisfactory as they contained less than 11.25 per cent. of dry substances, 15.7 per cent. were poor as they contained between 11.25 and 11.50 per cent. of dry substance, 209 samples contained 12—13 per cent. of dry substance, 36 samples over 13 per cent. dry substance, and 2 samples contained 15.80 and 16.39 per cent. dry substance. In Bremen the following results were obtained :—

Number of Samples.	Specific Gravity at 15° C.	Volume Per Cent. Cream.	Per Cent. Fat.	Per Cent. Dry Substance.
1887.	Per Cent.			
99 market milk .	1.0314	7.54	2.84	11.54
6 stall milk	1.0316	6.14	2.53	11.08
1888.				
87 market milk .	1.0318	8.23	2.98	11.62
23 stall milk	1.0310	7.59	2.98	11.48
1889.				
94 market milk .	1.0319	8.31	2.94	11.52
18 stall milk	1.0312	6.24	2.36	10.80

Butter.—In Bremen, of 109 samples examined, 49 contained foreign fats, 3 were pure margarine, many were rancid, and one contained casein, water, salt, and a little butter. Of 30 London butters one contained 35 per cent. and another 90 per cent. of foreign fats. Much butter is imported into England from Normandy as pure French butter which contains 70—80 per cent. margarine.

Lard.—Of 92 samples taken in Bremen 69 were adulterated with tallow and cotton-seed oil. Lard adulteration also goes on very largely in the United States.

Flour and Bread.—The per cent. of water contained in Amsterdam samples were, wheat flour, 11.3; barley flour, 12.1; rye flour, 13.2; rice flour, 11.4; potato flour, 19. Wheaten bread contained 32—40 per cent. moisture and 1.4—1.7 per cent. ash; rye bread, 2.5 per cent. ash.

Soda Water.—A Bucharest sample contained alum, which had been used to clarify the water, and another sample contained lead.

Beer.—Two Bremen samples contained salicylic acid. It has been enacted in Belgium that lead pipes shall not be used for beer machines.

Spices.—Of 8 samples of mace 3 were adulterated. The samples of pure mace contained about 11 per cent. water, 42 per cent. alcoholic extract, and 2 per cent. ash, whilst the adulterated samples contained about 5 per cent. water, 63 per cent. alcoholic extract, and 1.8 per cent. ash. Black pepper contains 5—5½ per cent. ash, and samples containing over 7 per cent. are adulterated with sand; this last spice is a very favourite one for adulterating.—A. L. S.

The Application of Aluminium for Vessels for containing Foods, &c. G. Rupp. Dingl. Polyt. J. 1891, 293, 19—21.

THE author has subjected aluminium in various forms, such as cups, canteens for the troops, and foil, to the action of different foods and liquids for a length of time varying from 4 to 28 days at the ordinary temperature. An analysis of the metal employed gave Al, 99.66; Si, 0.08; and Fe, 0.30. Besides observing the loss of weight after treatment he also estimated the aluminium in the food, &c. before and after treatment; the results are given in the table. The author also mentions that whereas aluminium in a finely-divided state is perceptibly oxidised by boiling water, the metal in bulk, with the same treatment, is practically unaltered. In conclusion he advocates the re-establishment of aluminium for containing vessels for foods, &c.

Method and Apparatus for Drawing off and Transporting Sterilised Liquids without being Contaminated with Germs. O. Imray, London. From "Calhera Fitz und Consorten," Berlin, Germany. Eng. Pat. 1191, January 22, 1891. 1s. 1d.

This invention has for its object the transport of sterilised fluids, e.g., milk in large quantities. The vessel is spherical and smooth on the inside to render cleaning easy, and is provided with protected orifices at the ends, to one of which may be attached a complex air filter for the removal of germs from the air admitted to replace the fluid drawn off. (For description of the filter we refer to the original.) Among the filtering materials are cellulose, wadding, and charcoal, the former two being regenerated by hot air. A cylinder of a compressed gas such as carbonic acid may be used instead of the air filter.—L. de K.

(B.)—SANITARY CHEMISTRY.

PATENTS.

Improved Method for Precipitating Solid Matter in Sewage, Purifying and Disinfecting the Effluent Water, and Solidifying and Preparing the Sludge for Use as Manure. J. Hardwick and L. A. Newton, London. Eng. Pat. 15,405, September 29, 1890. 6d.

The invention consists in first mixing the sewage with a sufficiency (to be determined if necessary by experiment) of a mixture of gypsum, salt, nitrate of lead, borax, alum,

and nitre, and in some cases also salicylic acid, hydrochloric acid, and caustic potash.

The deposit is finally made into a manure by mixing it with a compound of sulphate of lime, carbonate of lime, salt, sulphur, borax, and magnesite.

Besides yielding a highly purified effluent water, the inventors claim to produce a manure which, whilst possessing valuable fertilising properties, will destroy all insect life.

—L. de K.

Improvement in Apparatus for the Filtration, Aëration, and Purification of Water for Household or Drinking Purposes and the Like. B. L. Ray, London. Eng. Pat. 19,512, December 1, 1890. 6d.

The invention consists in the use of an outer filter case which may be of stone, glass, china, wood, or metal, a filtering pan which fits into the outer case by a broad rim. At the bottom of the filtering pan and descending from it, is a tube or square or oblong; and round the sides of this receptacle are a few fine holes for straining. This receptacle is for receiving a sterilised filtering medium. Inside the filtering pan is a ledge, and on this is placed a flat aërating strainer which fits the filtering pan and from the centre of strainer rises a funnel or pipe for the purpose of aërating the water. Air is admitted through holes in the rim of filtering pan and slight grooves on the rim of the outer case.

—L. de K.

Improvements in and Relating to the Treatment of Sewage and Sewage Deposits. H. Tatham, Burnley. Eng. Pat. 1225, January 23, 1891. 6d.

THE invention relates to the purification of sewage and the manufacture of manure.

The chief feature of the invention is a disintegrator, consisting of two rollers, one of which is spiked and the other plain, the former running the faster, which enables the blocks or cakes of the manure from the filter-press to be reduced to fine particles with rapidity and a very little cost.

—L. de K.

(C).—DISINFECTANTS.

PATENTS.

Improvements in Apparatus for Vaporising Oils and other Liquids for Medicinal and Disinfecting Purposes.

W. H. Spencer, St. Leonards-on-Sea. Eng. Pat. 8629, May 20, 1891. 8d.

THE invention "consists in improved apparatus for vaporising eucalyptus and other oils or materials possessing allied qualities, at such temperatures as have been found from experience to produce the highest remedial effects under varying conditions of disease, by charging the air with the vapour evolved to any desired degree of saturation over extended periods of time, without any further adjustment of apparatus after preliminary setting." For details the specification must be consulted.—L. de K.

Improvements in Sulphur Candles. S. B. Morss, New Jersey, and T. F. Bourne, New York, U.S.A. Eng. Pat. 18,434, October 27, 1891. 6d.

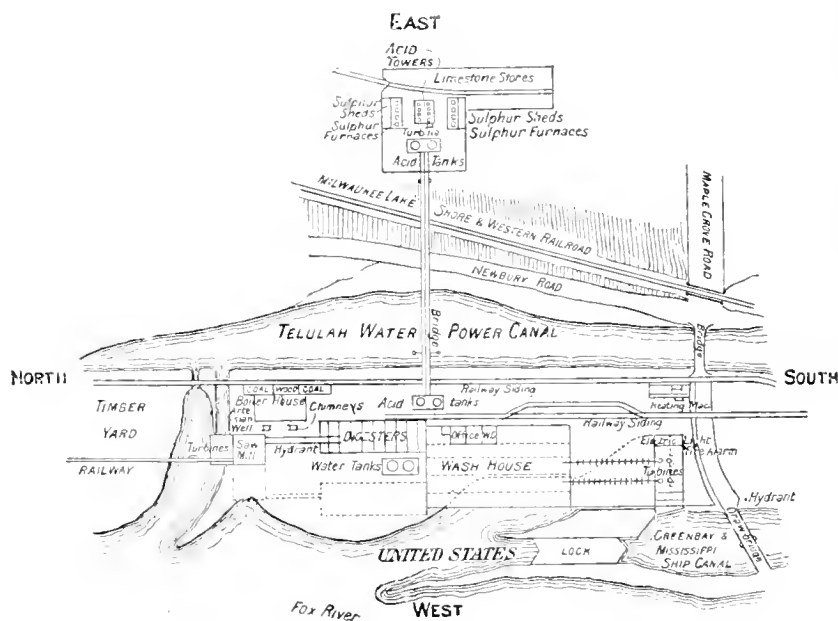

WHEN sulphur is moulded into a block or mass it becomes very hard and difficult to ignite when a flame is applied to its upper surface. Further, on account of the fumes that arise, a person cannot long remain in proximity to the candle.

The invention consists chiefly in undermining the surface of the candle so that a flame will attack and ignite the sulphur quickly and positively.—L. de K.

XIX.—PAPER, PASTEBOARD, Etc.

Description of an American Sulphite Cellulose Paper Mill. H. Wildhagen. Papier Zeit. 1891, 16, 2122—2124.

AN account is given of a large paper mill recently erected at Appleton, on the Fox river (Wisconsin), on the plan known as the Mitscherlich system. The water-power resources of the country are very large, due to the fact that in this section of the river, between Lake Winnebago and Greenbay (Lake Michigan) extending for about 30 miles, there are no less than 18 locks, the fall of which varies from 7 to 12 ft., the river all along its course being used to supply power to mills and factories. Lake Winnebago forms the natural reservoir for this supply, extending for about 40 miles in length and varying from 15 to 20 miles in breadth. At Appleton a weir 8 ft. high and about 750 ft. long gives power on the west bank of the river to various works. On the eastern bank, situate on an island formed by the Fox river, the Greenbay, and the Mississippi Navigation Canal and the Telulah Water Power Canal, lies the paper mill in question. The river is about 750 ft. wide at this point and is bridged by a wooden structure for vehicular and passenger traffic. Across this bridge is the Greenbay and Mississippi Canal, and thence communication is obtained across a swing-bridge with the island, which is about 250 ft. in breadth. Another bridge crosses the Telulah Water Power Canal on the east and affords communication with the mainland. Alongside the roadway thus formed lies the building containing the principal turbines; it is 100·5 ft. by 53, and contains one story only. The plant consists of four turbines of 100 horse-power each and one smaller one of 75 horse-power. In sets of two the former supply power to the wash-house by means of shafting, whereas the latter turbine drives the dynamos for electrically lighting the whole of the mill. The water for these turbines is drawn from the navigation canal. Between the turbine-house and the wash-house lies an open space, measuring 135 ft., upon which there is room for five paper machines. The wash-house, 142·5 by 263 ft., consists of one large hall subdivided into five sections merely by the columns supporting the roof. The centre section is 34 ft. high, the others being 20 ft. only, and a row of windows gives light to the centre of the building. Along this section is arranged the large machine for drying cellulose,

PLAN OF PAPER MILL, &c.

built up of 37 drying cylinders of 3.5 ft. diameter and two sieve cylinders. The two sections of the west side of the building are occupied by washing machines, pumps, troughs, depositing tanks, and other machinery, whereas the sections on the opposite side are taken up by offices, and will only be used for machinery in case of extensions. The three first-named sections have concrete floors, but the eastern portion of the building has only wooden flooring. Situate at the north-east corner of this building lies that containing the digesters, of which there are at present eight; this building has three storeys, and is 156.7 by 60.7 ft.: reference to the plan will, however, show that provision has been made for the addition of 12 further digesters. Here also the floor is concreted so that the pulp after being dropped from the digesters is simply flooded into the wash-house. On the third floor there is accommodation for sufficient wood for each digester, and as soon as one boiling is completed no time is lost in recharging with the wood from above. The wood is conveyed to the store just mentioned from the saw mills, which are about 100 ft. off, by means of a belt. The saw mills consist of a building 58 by 60 ft., containing on the ground floor the shafting for the bark-removing, sawing, grinding, and various other machinery placed in the upper floor. The refuse of shavings and sawdust, &c., is conveyed by a blower through an iron tube 24 in. in diameter to the boiler-house. In the saw mill there is, among others, one machine capable of working over 70 cords of wood into discs of 1.25 in. in thickness in 10 hours. The saw mills are driven by two 100-horse-power turbines mounted in an adjoining building facing north, here there is also a 25-horse-power turbine for driving a pump for the supply to the tower of water required for the preparation of the acid. Beyond the outlet from the Telulah Water Power Canal supplying power to this part of the mill lies the timber yard, with a capacity of several thousand cords of wood, and bounded in the east by a siding of the Milwaukee Lake Shore and Western railroad. The extensive narrow gauge lines of rail in this yard end in the upper storey of the saw mills, running up an inclined bridge. The boiler-house for supplying steam to the digesters and for heating the drying cylinders and buildings lying east of the saw mills, contains two batteries of water-tube boilers, each with a chimney of 125 ft. in height. The towers and sulphur furnaces lie to the east of the Telulah canal on a small hill about 65 ft. high. An iron bridge 420 ft. long gives access to this part of the mill, and carries the conduits for acid, water, steam, waste gases, and the electric current for lighting the bridge and tower. The nine towers are each 115 ft. high and are braced together by a staging 32 ft. wide and 44 ft. long; a building on the top, 32 by 44 ft. and 8 ft. high, bounded by a 8-ft. gallery, contains the water cisterns and systems of piping for each tower; it is heated so that this part of the plant is not liable to become frozen in the cold season. The lift for limestone is placed centrally in the tower and is driven by a small turbine 3 ft. in diameter, placed at the foot of the tower. The water for feeding this turbine is obtained from the turbine of 25-horse-power already mentioned in connexion with the saw mill; it is pumped to the top of the tower and is always kept running, because it is of great importance that the water required here should be as cold as possible. For this purpose it draws from an artesian well. North and south of the tower are the sheds for the sulphur furnaces and sulphur stores, and to the east lies the siding of the Milwaukee Lake Shore and Western railroad, conveying limestone and sulphur. Two tanks for the acid are placed by the canal side close to the bridge, and the liquid is conveyed through an 8-in. pipe across the bridge to two similar tanks placed on high stagings. From here it is conveyed direct to the digesters. The two water tanks are similarly placed on the other side of the digester, or boiling-house, and are supplied by two large double-acting pumps. These six tanks measure 24 ft. diameter by 12 ft. high each. The whole of the foundations and canal walls are in quarry stone and Portland cement, and the buildings in yellow brick and mortar. The mill has a daily output of 25,000 kilos. of dry cellulose.—H. S.

The Paper Industry of Lower Austria. Papier Zeit. 1891, 16, 2142.

THE following is an extract from the report of the Vienna Chamber of Commerce on the paper industry of Austria in 1890:—

The condition of this industry has not experienced any improvement in 1890 as compared with the previous year. The productive capabilities of the Lower Austrian paper mills, which are on the whole favourably situated, remained unaltered, but the concerns did not pay as good a dividend as in the previous year. The over-production, which had in years gone by sought the export markets and had thus relieved the home market, has now to be provided for elsewhere, as many countries, formerly customers, are now large manufacturers themselves. Thus Roumania, the United States, and on account of the disturbances, South America also, were lost in rapid succession.

The export business is represented as being reduced to a mere matter of calculating freights, and owing to the high railway rates in Austria and the equally unfavourable freights charged by the Austro-Hungarian Lloyd, such calculations were rarely favourable to Austrian industry.

As compared to the development of the manufacturing establishments of this trade and the number of mills employed therein, the home demands appear very modest. Although intended to be assisted by extensive printing, newspaper, and publishing combinations, these do not exist on a sufficient scale to be of real value. In fact the few newspapers sold, the small number of publishing offices and the various public demands, are only sufficient to absorb a portion of the output.

Repeatedly the mill-owners have pointed out that Germany imports large quantities of printed paper into Austria, and that by her publishing monopoly, she not only does immense damage to the Austrian paper industry but moreover ruins the printing and bookbinding trades. But still more opposed to the interests of the industry than Germany, with her duty-free importations, is the antiquated press-law, with its fiscal measures, such as newspaper-stamps, securities, &c., which make it impossible for a printing and publishing industry of any value to the country, to exist.—H. S.

PATENTS.

Improvements in Apparatus for Straining or Screening Paper Pulp. W. P. Thompson, Liverpool. From P. R. Thorn, Appleton, U.S.A. Eng. Pat. 18,169, November 11, 1890. 8d.

In the ordinary method of agitating pulp screens, one end only is moved. According to the present invention both ends are agitated and the horizontal motion which is usually given is dispensed with as being unnecessary and injurious.

—E. J. B.

Improvements in Self-registering Apparatus for Measuring the Tensibility and Breaking Strain of Paper and other Light and Flexible Material. F. Leunig, London. Eng. Pat. 18,431, November 15, 1890. 6d.

THIS invention cannot be suitably described without reference to the drawings.—E. J. B.

Improvements in the Manufacture of Paper for Cheques and like Documents. R. C. Menzies, Musselburgh, and E. J. Bevan, London. Eng. Pat. 748, January 15, 1891. 4d.

FERROCYANIDE of manganese, starch, iodide, and iodate of potassium or sodium, and sulphate of manganese are incorporated with the paper.—E. J. B.

An Improvement in the Manufacture of Pulp for Paper Making and other Purposes. R. N. Redmayne, Newcastle-on-Tyne. Eng. Pat. 927, January 19, 1891. 8d.

INSTEAD of discharging the contents of a pulp boiler into a blow-off pit situated below the boiler, the inventor utilises the pressure of steam inside the boiler and causes it to force the pulp to a higher level so as to be ready for the subsequent operations, and thus save the cost of handling.

—E. J. B.

An Improvement in the Process for the Simultaneous Production of Cellulose and Oxalic Acid from Vegetable Fibrous Substances. J. Lifschütz, Grünau, Germany. Eng. Pat. 1824, January 31, 1891. 6d.

ACCORDING to this process, wood, jute, straw, and similar materials are treated with a mixture of dilute nitric and sulphuric acids. The brown vapours evolved, which consist of N_2O , NO and NO_2 , are reconverted into nitric acid. No N_2O is evolved. The acid liquid is used for other operations, the temperature being gradually increased as the nitric acid becomes exhausted. When this occurs the oxalic acid is crystallised out by cooling.

The ligneous material after the action of the nitric acid is converted into pure cellulose by treatment with a weak alkaline solution.—E. J. B.

Improvements in the Treatment of Fibrous Plants for the Manufacture of Paper Pulp. J. Beveridge, Gravesend. Eng. Pat. 2872, February 17, 1891. 6d.

STRAW, esparto, and similar fibrous plants contain considerable quantities of silica, which is not removed by treatment with acid sulphite solutions. The inventor proposes an additional treatment with an alkali which may be applied either before or after the acid sulphite treatment.

—E. J. B.

Improved Machine for Making Parchmentised Fibre and the like. C. N. Robinson, Wilmington, U.S.A. Eng. Pat. 15,222, September 8, 1891. 6d.

THE object of this invention is to prevent the "buckling" of sheets of parchment paper which occurs in the ordinary method of manufacture. It is obtained by the use of special mechanical appliances which cannot be well understood without reference to the drawings accompanying the specification.—E. J. B.

New Manufacture of Composition for Blotting or Absorbing Liquids. A. Bürkel and C. Osterwald, Bremen, Germany. Eng. Pat. 16,921, October 5, 1891. 4d.

925 PARTS by weight of gypsum, 50 parts of wool fibre, 10 of lime, 10 of sodium bicarbonate, and 5 parts of sulphuric acid are mixed together with an equal quantity of water. The paste is moulded in the form of a block, which, when dried, is said to be an efficient absorbent of liquids.

—G. H. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Sulphonic Acids of some of the Cinchona Alkaloids. O. Hesse. *Annalen*, 1891, 267, 138—142.

FUMING sulphuric acid converts the four chief cinchona alkaloids into sulphonic acids, but since the action of strong sulphuric acid is to form the iso-bases iso-quinine, iso-conquinine, iso-cinchonidine, and iso-cinchonine, the sulphonic acids are to be regarded as derived from these iso-bases. To prepare the sulphonic acids, the alkaloids, either as dehydrated mono- or tri-sulphates, are dissolved in the fuming sulphuric acid, colourless solutions being obtained, which are neutralised by baryta, and the barium salt of the sulphonic acid decomposed by sulphuric acid. The resulting solution is evaporated at 50° — 60° C., when a light-brown residue is obtained, which after drying can be ground to a light-brown or flesh-coloured powder.

Isoquinine Sulphonic Acid, $C_{20}H_{23}N_2O_2 \cdot SO_3 \cdot OH$, is readily soluble in water. The solution is only slightly acid, it has a blue fluorescence, and is strongly levo-rotatory. It gives an intense dark-green colouration with ammonia and chlorine water. Platinic chloride forms a readily soluble double chloride, whilst auric chloride yields a yellow flocculent precipitate which, when dried at 100° C., has the composition $C_{20}H_{23}N_2O_2 \cdot SO_3 \cdot OH \cdot HCl \cdot AuCl_3$.

Isoconquinine Sulphonic Acid is isomeric with the above and closely resembles it in its properties. It is slightly dextro-rotatory in aqueous solution.

Iso-cinchonidine Sulphonic Acid, $C_{19}H_{22}N_2OSO_3 \cdot OH$, gives no precipitate with platinic chloride, but a yellow flocculent precipitate with auric chloride. It is dextro-rotatory in aqueous solution.

Iso-cinchonine Sulphonic Acid resembles the preceding. It is slightly soluble in water, has an acid reaction, and gives precipitates both with platinic and with auric chlorides. The sulphonic acids of quinine and of cinchonidine are obtained by treating the well-dried tetrasulphates of these bases with acetic anhydride. The sulphates of the sulphonic acids which result when dissolved in hot water and neutralised by ammonia yield the free sulphonic acids, which may be purified by recrystallisation from hot dilute alcohol.

Quinine Sulphonic Acid, $C_{20}H_{23}N_2O_2 \cdot SO_3 \cdot OH + H_2O$, forms small white prisms, difficultly soluble in hot water, which lose their water of crystallisation at 120° C., and then melt with decomposition at 209° C. The hydrochloric acid solution of the sulphonic acid is levo-rotatory— $[\alpha]_D = -182.2^{\circ}$ at 15° C. The platinum double chloride—

crystallises in needles.

Cinchonidine Sulphonic Acid, $C_{19}H_{21}N_2O \cdot SO_3 \cdot OH + H_2O$, also forms small white needles difficultly soluble in water, which melt at 225° C. The platinum double chloride forms orange-coloured needles which contain 3 molecules of water of crystallisation. It is levo-rotatory in hydrochloric acid solution $[\alpha]_D = -140^{\circ}$ at 15° C.—C. A. K.

Compounds of Quinine with Hydrochloric Acid. O. Hesse. *Annalen*, 1891, 267, 142—144.

QUININE hydrochloride crystallises in white needles with two molecules of water of crystallisation, which it loses at 120° C., without previously melting. The requirement of the German Pharmacopœia that this salt should melt at 75° C. is therefore not fulfilled by the pure hydrochloride. The dehydrated salt melts at 158° — 160° C. without change, and is not converted into quinine, as stated by Pasteur. If an aqueous solution of the hydrochloride saturated at 15° C. be allowed to stand for some time at a low temperature (about 0° C.), large octahedral crystals belonging to the monoclinic system separate out. These differ from the usual long asbestos-like needles of the salt in containing 3 instead of 2 molecules of water of crystallisation. Acid

quinine hydrochloride, the salt specially applicable for subcutaneous injection, is formed by treating the bisulphate with the equivalent quantity of barium chloride or by evaporating a solution of the normal hydrochloride to which a molecule of hydrochloric acid has been added. It forms groups of concentric needles having the composition $C_{20}H_{24}N_2O_2 \cdot 2HCl$, which can be dried without change at $110^\circ C$. It also separates as a gelatinous mass, which becomes crystalline on gentle warming. The salt corresponds therefore in composition to the hydrochloride of iso-quinine, whence the composition of the latter cannot serve to distinguish the two bases, quinine and iso-quinine, as has been suggested by Lippmann and Heissner (this Journal, 1891, 945—946).—C. A. K.

The Action of Methyl Iodide on Cupreine and on Quinine.
O. Hesse. *Annalen*, 1891, **266**, 240—245.

QUININE, when boiled with methyl iodide in methyl alcohol solution, is converted into quinine-monomethyl iodide—

whilst when the mixture is heated in a closed vessel to 80° — $100^\circ C$, the dimethyl iodide is formed. The same product results when the reaction is allowed to take place at the boiling point of the mixture in presence of caustic soda or of sodium methylate. It forms yellow tables having the composition $C_{20}H_{24}N_2O_2 \cdot 2CH_3I + 3H_2O$, which lose their water of crystallisation completely in the exsiccator. The dehydrated dimethyl iodide melts at 158° — 160° , which agrees with the melting point determined by previous investigators. Silver chloride converts this dimethyl iodide into the corresponding chloride, from which both platonic and auric double chlorides can be prepared, both of which are difficultly soluble in water.

Cupreine, when heated with an excess of methyl iodide in methyl alcohol solution, yields the monomethyl iodide, whilst the dimethyl iodide results by prolonged heating in a closed vessel to 80° — $100^\circ C$. The latter forms prismatic crystals having the composition—

corresponding, therefore, in composition to the quinine dimethyl iodide. It loses its water of crystallisation in the exsiccator and melts with decomposition at $210^\circ C$. When treated with silver chloride the corresponding dimethyl chloride is formed, which yields an orange-coloured, granular, difficultly soluble platinum double chloride.

Cupreine dissolved in methyl alcohol is converted into quinine dimethyl iodide when treated with 1 part by weight of sodium (in the form of concentrated caustic soda or of sodium methylate) and 6 parts by weight of methyl iodide. (Compare this Journal, 1891, 723 and 770).—C. A. K.

Iso-cinchonine. O. Hesse. *Annalen*, 1891, **266**, 245—248.

THE author has shown that the alkaloid *cinchonigine* obtained by Jungfleisch and Léger (this Journal, 1891, 724) is identical with *iso-cinchonine*, which is formed by the action of strong sulphuric acid on cinchonine. Jungfleisch and Léger have expressed the opinion that this *iso-cinchonine* contains *cinchoniline* (Compt. Rend. **112**, 942) which is, however, not the case. Nevertheless *cinchoniline* is formed in small quantity, together with *iso-cinchonine*, when cinchonine sulphate is treated with sulphuric acid. *Iso-cinchonine* is not converted into *cinchoniline* by further treatment with sulphuric acid, and the author is of opinion that the formation of this second alkaloid is due to the presence of a second isomeric alkaloid in the so-called "pure" cinchonine sulphate.

Other points referring to the probable presence of a second cinchonine are discussed in the paper.—C. A. K.

A New Alkaloid from Javanese Coca Leaves. F. Giesel. *Pharm. Zeit.* 1891, **36**, 419.

A SMALL-leaved Javanese coca plant contains about 2 per cent. of alkaloid but very little cocaine.

The chief alkaloid present appears to be one closely resembling dextro-cocaine obtained by Einhorn from dextro-ecgonine. The base is not markedly optically active; concentrated hydrochloric acid converts it into benzoic acid and the hydrochloride of an ecgonine. The new base is most probably an isomer or homologue of cocaine.—A. L. S.

Fatty Matter and Ethereal Oil of Sabadilla Seed.

E. Opitz. *Arch. Pharm.* 1891, **229**, 265.

By exhausting ground sabadilla seeds with light petroleum and distilling the extract in vacuo, the crude fat is obtained as a brownish-green liquid readily soluble in alcohol, ether, and benzene. When submitted to steam distillation this product yields about 3.2 per cent. of ethereal oil and the residual fat then has the following percentage composition:—oleic acid, 50; palmitic acid, 36.30; cholesterol, 4.12; glycerol, 9.55; whilst the ethereal oil, on fractionation, distils mainly between 220° — 250° , the distillate having a specific gravity of 0.907, a slightly greenish colour, and an odour resembling turpentine; it consists of ethyl and methyl salts of hydroxymyristic and veratric acids, aldehydes of the lower fatty acids and of high-boiling polyterpenes.—D. A. L.

Larch Turpentine. E. Valenta. *Centr. Org. f. Waarenkunde u. Tech.* 1891, **1**, 141.

On distillation with superheated steam, pure Tyrolean larch turpentine yields 15 per cent. of crude ethereal oil. The residue, after freeing from water and remaining oil in vacuo, is an amber-yellow coloured resin, and when dissolved in acetone is dextro-rotatory. The greater part of it dissolves in 95 per cent. alcohol the insoluble residue—a brown resin—does not apparently exist in the original larch turpentine, but is produced during the heating in vacuo. The alcoholic solution contains, in addition to a colloidal resin, abietic acid. After fractional distillation, the principal portion of the ethereal oil obtained boils at 158° , is a clear colourless laevo-rotatory oil with pleasant odour, has a specific gravity of 0.8604 at 15° and an iodine number=201. The portion boiling between 159° — 165° appears to be a mixture of many turpentine oils.—D. A. L.

On the Production of Sulphate of Quinine. E. Jungfleisch. *Bull. Soc. d'Encouragement Ind. Nat.* 1891, **6**, 604—610.

No other important chemical has diminished in price during the last 10 years so much as sulphate of quinine. The Jahresbericht, published by Zimmer and Co. of Frankfort-on-the-Main, gives the following limits for the prices per kilogram, for the last few years:—

	Francs.
1880	454—443
1881	531—306
1882	444—319
1883	322—262
1884	322—155
1885	190—105
1886	134—88
1887	106—65
1888	88—56
1889	60—38

The introduction of other antipyretics has been suggested as a reason for this decrease in price, but the fact that the total consumption of sulphate of quinine increases by about one-tenth each year negatives this supposition. Speculation is equally incapable of producing a regular diminution in the price, nor is it due to improvements in manufacturing processes. The true explanation lies in the reduction of

the cost of the raw material. Improved methods of culture have yielded far better results than were expected, both in the quantity of the bark and the percentage of alkaloid it contains, which far surpasses the percentage in the best forest barks of South America. Ceylon is the country which yields the largest quantity of cultivated bark. The following figures are taken from *The Ceylon Handbook and Directory* :—

CINCHONA BARK EXPORTED FROM CEYLON TO EUROPE.

	Lb.
1875-1876*	16,812
1876-1877	56,589
1877-1878	178,497
1878-1879	373,511
1879-1880	1,208,518
1880-1881	1,207,720
1881-1882	3,069,895
1882-1883	6,925,538
1883-1884	11,402,947
1884-1885	11,678,390
1885-1886	15,361,912
1886-1887	14,438,260
1887-1888	11,704,932
1888-1889	11,798,465

The diminution of the yield during the last few years is attributed to parasitic diseases. In India, on the plantations begun in 1862, Government has now more than six million cinchona trees under cultivation, and private individuals possess about the same number. The exports of bark from these two sources (from October 1st to September 30th of each year) have been as follows :—

	Lb.
1880-1881	639,258
1881-1882	428,497
1882-1883	641,608
1883-1884	306,419
1884-1885	745,730
1885-1886	857,040
1886-1887	1,285,900
1887-1888	1,449,315
1888-1889	3,074,098

These numbers do not represent the total production of sulphate of quinine, as there are factories in Bengal which work up a portion of the bark on the spot. In 1889 these factories produced 2,191 lb. of sulphate of quinine and 6,384 lb. of a febrifuge consisting of a mixture of alkaloids.

In Java, where the area of the Government plantations forms a much smaller proportion of the whole, the exports of bark (from July 1st to June 30th of each year) have been as follows :—

	Dutch Pounds.
1883-1884	1,104,534
1884-1885	1,195,479
1885-1886	1,531,156
1886-1887	2,230,275
1887-1888	3,742,025
1888-1889	4,415,031

Thus the colonies in Asia export to Europe a total of nearly eight million kilos. of cinchona bark. They will in all probability soon manufacture all the sulphate of quinine they need for their home consumption. In South America, as the forests, which for a long time were the only source of cinchona bark, have become impoverished, cultivation has also been commenced and will probably soon attain large proportions. It is impossible to obtain complete statistics on the subject, but the exports of cultivated bark rich in alkaloids from Bolivia to the London market may be quoted :—

	Bales.
1885	2,530
1886	3,370
1887	7,190
1888	7,810
1889	9,552

* From October 1st to September 30th.

In many other countries, Jamaica, Réunion, St. Thomas, the Fiji islands, &c., the plantations are too young to yield, but they will soon be productive and export to Europe.

There are of course many varieties of cinchona of unequal value, and the number has been increased by hybridisation. In the same species the *natural bark*, *mossed bark*, and *renewed bark* (*écorce renouvelée*) contain very different percentages of quinine, the last being the richest. But there can be no doubt of the general increase in the percentage of quinine contained in the bark; of late years it has not been unusual to meet with lots yielding 10 per cent. and more of sulphate of quinine. It seems probable that the market value of this product will not again increase to a figure which will put it beyond the reach of the poor.

The methods for the extraction of quinine sulphate have not changed since 1878, but the product has been more carefully purified. When manufacturers employed, almost exclusively the bark of *Cinchona calissaya*, which contains but a small percentage of the other alkaloids and notably of cinchonidine, the methods of Pelletier and Caventou sufficed to give a fairly pure product. But the use of cultivated bark, which contains a large percentage of the other alkaloids, introduced into the commercial sulphate a considerable amount of sulphate of cinchonidine, which crystallises with sulphate of quinine, and indeed, causes it to crystallise in silky needles and gives it the characteristic appearance of "light" quinine sulphate. One per cent. of sulphate of cinchonidine suffices to produce this silky appearance, and this is not changed by the addition of an excess. A few years ago, when the bark of *Remigia*, which contains no cinchonidine, was first treated, the latter alkaloid was added, as the pure solutions yielded large brilliant needles unfamiliar in commerce; for the same reason the bark of *Cuprea* was never treated without being previously mixed with other barks. These circumstances led European manufacturers, when the cultivated barks were first employed, to produce samples of sulphate of quinine far too largely admixed with sulphate of cinchonidine, a state of things which led to new regulations for the pharmacopœia in different countries. The French Code in 1884, making use of Kerner's method of analysis, prescribes that 5 cc. of a mother liquor obtained at 15° C. after treatment of 1 gm. of the official salt with 10 cc. of luke-warm water, shall remain perfectly limpid for 24 hours after the addition of 7 cc. of a solution of ammonia of density 0.96. The manufacturers considered these regulations severe. However, the new Austrian pharmacopœia prescribed the use of 7.5 cc. of ammonia, which is only slightly less severe a test; and the pharmacopœias of Russia, Finland, Sweden, the United States, and Japan adopted nearly the same test; the Dutch pharmacopœia has reduced the amount of ammonia to 5 cc. and the German pharmacopœia of 1890 to 4 cc. It seems probable, therefore, that before long only pure ("heavy") sulphate of quinine will be used; and this salt may be recognised by its crystalline appearance which resembles that of zinc sulphate. The only objection of any weight to the employment of the pure salt is that the expense necessary in transforming a nearly pure into an absolutely pure product may be disproportionate to the advantage gained. The author thinks, however, that this expense cannot be very great.

4. Sulphate of quinine manufacturers produce at least four qualities of substance. (1.) The pure salt or "heavy sulphate" of which the use has been hitherto extremely limited chiefly on account of its unfamiliarity to the members of the medical profession; (2.) and (3.) Products satisfying the requirements of the German and Dutch pharmacopœias; and (4.) Products for the others of the above-mentioned pharmacopœias, and containing four to six per cent. of sulphate of cinchonidine. Other products may have a certain commercial importance but have no "legal status" in civilised countries.

5. It is evidently a waste of energy to ship bark to Europe of which only a small percentage by weight is utilised. However, the inferiority of native labour and the dearth of acids in the countries where the bark is grown are an obstacle to the establishment of factories on the spot. Nevertheless, the English in India are developing an industry which seems likely to compete with that of Europe. In

South America less progress has been made, but the first step has been taken. M. Manuel Jijon has set up a factory at Quito which supplies the whole of Ecuador, and has begun to export a product which has a very good appearance. The sulphuric acid necessary is manufactured on the spot from native sulphur.—P. J. H.

PATENTS.

Improvements in Coatings for Therapeutical Purposes. H. Lake, London. From "Ichthyol Gesellschaft Cordes, Hermann, and Co.," Hamburg, Germany. Eng. Pat. 588, January 12, 1891. 6d.

This invention relates to an improved coating for therapeutical purposes into which the remedy is incorporated.

The remedy, either solid or dissolved, is mixed with pure dry starch, and if this should fail to keep the mass homogeneous, certain portions of albumen, casein, or other similarly acting substances should be added. The inventors give a few instances.

An ichthyol coating may be obtained by sprinkling wheat-starch with half its weight of water and mixing with an equal weight of ichthyol; 1 to 1.5 per cent. of a strong solution of albumen is then added, and the mixture triturated until fit for use.

A glycerin coating is obtained by mixing in the same manner 30 per cent. of glycerin with 30 per cent. of starch meal, 15 per cent. of water and 25 per cent. of gum arabic; or 40 per cent. of glycerin, 40 per cent. of starch, and 20 per cent. of a strong solution of casein.

A chloride of calcium coating is prepared by mixing about 40 per cent. of its 50 per cent. solution with 40 per cent. of starch meal, 10 per cent. of water, and 10 per cent. of a concentrated solution of albumen.—L. de K.

A New or Improved Manufacture of Eucalyptus Products for Various Useful Purposes. E. Dean, Epsom. Eng. Pat. 16,910, October 5, 1891. 4d.

THE leaves are dried in the sun or by artificial heat, and after selection cut or wrapped to be used as a substitute for tobacco, for smoking in pipes or in the form of cigars. The leaves and fibres may also be used for the stuffing of beds, mattresses, bolsters, pillows, and the cushions of chairs and sofas. The leaves, whether alone or combined with tea leaves, may be used for fumigating rooms, or, when ground, used as a snuff, for tooth powder, or combined with the fats employed in making soap and candles. The gum it is proposed to make into lozenges for the throat and chest, also for plasters and poultices. The seed is to be ground and used with or without ground gum and leaves in making bread.—L. de K.

Action of Light on Silver Chloride. W. Guntz. Bull. Soc. Chem. 1891, 3, 140—145.

AFTER reviewing former work on the subject, the author states that he has obtained by boiling with a reversed condenser for some hours a modification of AgCl , which is reduced by ferrous oxalate in the dark. He has proved that in vacuo it is coloured by light, and that in air chlorine is given off, there being loss of weight. In these cases some Ag_2Cl is formed which was identical in colour and properties with that obtained by the double decomposition of Ag_2F . He also states that with the formation of Ag_2Cl by light there is an absorption of heat of 28 cal., and that this explains why the action is facilitated by the addition of organic or mineral substances capable of absorbing chlorine with evolution of heat. Ag_2Cl is further decomposed by light into $\text{Ag} + \text{Cl}$. The author also mentions that Ag_2Cl is very opaque to light, a film of silver chloride being exposed for some days being only decomposed to the depth of $\frac{1}{10000}$ mm. Applying his results to photographic matters, he states that a very slight exposure is sufficient to start the process of reduction in the developing solution, and the chlorine then liberated supplies sufficient heat by its action on the developer to continue the decomposition of the AgCl , and this explains the fogging of plates by over-development; also that this unequal state of equilibrium explains how electricity, mechanical, or electro-chemical action may produce complete reduction in the developer.—J. C. C.

PATENT.

Means of Enlarging Photographic Gelatine Films by the Aid of Chemical Means and without the Aid of Enlarging Apparatus. A. J. E. Hill, Norbiton. Eng. Pat. 16,125, September 23, 1891. 6d.

THE film mounted on glass or other support after developing, fixing, and washing, is immersed in a bath composed of hydrofluoric acid 1 part, citric (or other vegetable acid) 4 parts, glacial acetic acid 1 part, glycerin 1 part, and water 32 parts by weight. In this the film separates from its support enlarging at the same time; it is then washed, and allowed to dry spontaneously on its final support. If further enlargement is required, it is treated again in the same manner. The inventor also claims the addition of sulphate of copper or iron to the bath to prevent loss of density by the action of the acids on the silver.—J. C. C.

XXII.—EXPLOSIVES, MATCHES, Etc.

Further Experiments on the Behaviour of Explosives in Fiery Mines. H. Lotmann. Zeits. f. Berg-Hütten u. Salinenwesen, 1891, 39, 183. (Compare this Journal, 1889, 419.)

THE author's observations have confirmed the decision of the Prussian Fire-damp Commission as to the danger of "black powder," but have proved their theory that the safety of an explosive in the presence of fire-damp or coal-dust is nearly proportional to the amount of gas evolved on explosion, to be untenable.

Ammonium oxalate was substituted for the charcoal in ordinary black powder with a view of lessening the hot gases evolved by its explosion, but the explosive force was thereby very seriously diminished without an accompanying increase in safety. Further experiments were made with Seidler's explosives (D. R. Pat. 46,205), diazonaphthalene-monosulphonic acid and diazobenzenesulphonic acid being employed. Their behaviour to fire-damp and coal-dust was favourable, but they are put beyond the pale by the dense and intolerable smoke which they yield.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Drawings from Photographs. Papier Zeit. 1892, 17, 92.

THE drawing is made in ink on a silver print which has been fixed but not toned. The print is first washed in a weak solution of soda in alcohol, and is then bleached by flooding several times with an alcoholic solution of potassium cyanide, made by mixing a saturated solution of the cyanide with 95 per cent. alcohol; finally the print is washed several times with alcohol.—J. C. C.

Experiments with the ordinary dynamites—kieselguhr dynamite, blasting gelatin, and gelatin dynamite—confirmed the former results, and showed in addition that immediate contact of the explosive with coal-dust increases the necessity for priming, and that tamped explosives are in general more dangerous than free cartridges.

"Moist dynamites" (*Wetter-dynamite*) were first prepared by Müller by the addition of salts containing water of crystallisation to dynamite; such are "crystal-soda-kieselguhr-moist-dynamite," "ammonium-oxalate-moist-dynamite" (45 per cent. ammonium oxalate, 15 per cent. sodium nitrate, 40 per cent. nitroglycerol with kieselguhr), and "bicarbonate-moist-dynamite" (kieselguhr-moist-dynamite with 35 per cent. of sodium bicarbonate). Ammonium-oxalate-moist-dynamite proved safe, and bicarbonate-moist-dynamite is so safe that it can be used even in hot, fiery mines. Such explosives, however, should only be regarded as expedients, being uneconomical, because a large portion of the energy of the explosive is consumed in vaporising the added substances; much of the heat being thus employed, the products of the explosion are cooler. A "magnesium-sulphate-moist-dynamite" is marketed in Belgium and England.

The "carbonite" adapted for fiery mines is essentially a dynamite containing organic substances rich in carbon, such as sugar, starch, and cellulose. Such a one, analysed in 1888, gave the following percentage composition:—Nitroglycerol, 17.76; nitrobenzene, &c., 1.70; soda, 0.42; potassium nitrate, 34.22; barium nitrate, 9.71; cellulose, 1.55; cane-sugar, 34.27; moisture, 0.36. Carbonite is safe, but the quantity of carbon monoxide in its after-damp is very objectionable.

Explosives of the Sprengel class are objectionable by reason of their fluidity and their requiring a stronger detonator than dynamite explosives. "Securite" has given good results; its composition has undergone considerable change, and now consists of dinitrotoluene, ammonium nitrate, and potassium nitrate. Roburite is an explosive of the securite type and is safe. Three sorts of Favier's explosives were used. "Explosiv Favier" consists of 88 per cent. ammonium nitrate and 12 per cent. of dinitro-naphthalene; "Antigrison (anti-fire-damp) Favier" consists of 90 per cent. of "Explosiv Favier" and 10 per cent. of ammonium chloride; the third sort is for blasting in the absence of fire-damp, and contains in its compressed portion 79 per cent. of sodium nitrate and 21 per cent. of dinitro-naphthalene, while its mealy portion consists of "Explosiv Favier." The first two sorts proved favourable.

Hellhoffite is not widely applicable because of its concentrated nitric acid; but by substituting nitrates for the nitric acid, and nitrated animal products for the organic substances, after the manner of Sprengel, a safe and practicable explosive was obtained.—A. G. B.

On an Explosive Compound formed by the Action of Baryta-Water upon Chromic Acid in presence of Oxygenated Water. E. Pechard. *Compt. Rend.* 1891, 113, 39—41.

BARYTA-WATER exercises a curious action upon chromic acid to which oxygenated water has been added; a buff-coloured precipitate is produced which when dried detonates violently on percussion, or when heated. When heated at the bottom of a test-tube it detonates sharply and leaves a residue of neutral barium chromate mixed with a small excess of barium oxide. The dried precipitate is not decomposed by contact with water; after being treated with water and again dried it detonates as before. In contact with dilute sulphuric acid a blue colouration is produced which disappears rapidly with evolution of oxygen. In order to analyse the substance, it is mixed with a large excess of sand (previously washed with hydrochloric acid and carefully dried) and is deflagrated in vacuo. The amount of oxygen is measured by volume, and after treatment with dilute hydrochloric acid, the barium is estimated as barium sulphate, and the chromium as Cr_2O_3 . The analyses

appear to show that the dried precipitate consists mainly of a substance having a composition corresponding to the formula BaCrO_5 or $\text{BaO}_5 \cdot \text{CrO}_3$.—D. E. J.

PATENTS.

Improvements relating to the Manufacture of Explosives and to Apparatus therefor. E. J. Ryves, Crayford. Eng. Pat. 298, January 7, 1891. 6d.

THE object of this invention is to overcome a difficulty stated to arise when smokeless powders are used. According to the inventor, when powders are used in rifles, the products of which are entirely gaseous, the barrel is left so clean that the succeeding bullets experience great and varying degrees of friction. He proposes to obviate this by using an explosive compound of the following ingredients, which may be in the proportions given:—

Trinitro cellulose	50	50	75
Nitroglycerin.....	48	48	24
Castor oil.....	2	2	1
Magnesium carbonate	2	2	1
Cotton paper pulp	5	8	5

—W. M.

The Treatment of Cellulose for the Manufacture of Cellulose Nitrates or Gun-Cotton. J. Y. Johnson, London. From "Zellstoff-fabrik Waldhof," Mannheim. Eng. Pat. 336, January 7, 1891. 8d.

THE main feature in this invention is the disintegration of wood pulp, which has been freed from incrusting matters and soluble constituents, in a suitable machine, it being found that the degree of nitration and stability of the product depends greatly on the fineness of division of the cellulose before treatment with the nitrating acid mixtures for the preparation of gun-cotton.—W. M.

Improvements in the Manufacture of Gunpowder and in Apparatus therefor. G. G. André, Dorking, and C. H. Curtis, London. Eng. Pat. 843, January 15, 1891. 6d.

THE apparatus "consists essentially of a stationary cylinder with slot in the bottom, a perforated ring rotated thereon," and a roller which is rotated against the ring. The plastic mass as it comes from the kneading machine is fed in between the rotating cylinder and roller, and in this manner the perforations become filled with the plastic mass. The interior cylinder is supplied with water under pressure, and on the filled perforations coming opposite the slot in the bottom the water forces the pellets out into any suitable receiver.—W. M.

A New Manufacture of Explosives. M. Reuland, Dortmund, Germany. Eng. Pat. 11,713, July 9, 1891. 6d.

MELTED naphthalene has the property of penetrating anhydrous nitrate of ammonia so that the resulting mixture remains unaltered even in air saturated with moisture. The new explosive is prepared by intimately mixing nitrate or "humate of ammonia" with melted naphthalene. Such a mixture is not hygroscopic, nor is it affected in any way by moist air. "These explosives can be exploded only by means of a very intense thin flame. They are therefore unaffected by falling shock and change of temperature."

—E. J. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

A New Siphon. F. Konther. Chem. Zeit. 1891, 15, 1126.

The author has devised the form of siphon shown in the Figure.

A NEW SIPHON.

It consists of a wide glass tube which is sufficiently drawn out at one end to allow an india-rubber tube to slip over it, a cork provided with two holes for the insertion of glass tubes being fitted in the other end. To use the apparatus the bent glass tube is closed with the finger, the pinch-cock on the rubber tube opened, and the liquid drawn up the straight glass tube until the upper vessel is two-thirds full. The finger is then removed and air admitted into the upper vessel until the liquid commences to run out of the bent tube, the pinch-cock being thereupon closed.

The wide tube must obviously be of greater capacity than the two smaller tubes combined.—E. B.

Simple Method of Preventing Tumultuous Boiling.

E. Pieszczyk. Chem. Zeit. 1891, 15, 1126.

IRREGULAR ebullition of alcohol, petroleum, benzene, &c., may be prevented by placing a glass tube 5–8 cm. long and 5–10 mm. wide in a vertical or nearly vertical position at the bottom of the distilling vessel. The tube is kept in position by a platinum wire—terminating preferably in a loop—fused into its upper end, which is closed.—E. B.

Behaviour of Glass Surfaces towards Water, and Selection of Glass Vessels for Chemical Purposes. F. Mylius and F. Foerster. Zeits. f. Instrumentenkunde, 1891, 11, 311.

FOR the investigation of the action of water on glass surfaces the authors use millinormal sulphuric acid for solution containing more than 0.1 mgrm. of alkali (reckoned as sodium), but for quantities below this:—the colourless alkaline solution is shaken with some concentrated ethereal solution of iodo-eosine and the amount of alkali is estimated from the reduction in tint observed by comparison with a standard. Neutral water obtained by distilling ordinary distilled water to which a little sulphuric acid had been added to retain ammonia, was employed in the author's experiments on the action of water and atmospheric agencies on glass, and the action of glass on water. Useful comparisons may be made by exposing neutral water for similar periods in glass vessels from different manufacturers, and then examining the solutions.

From their various experiments the authors have observed:—1. That the action of cold water on glass is at first very rapid, but soon becomes much slower; the slackening is attributed to the formation of an exhausted and difficultly permeable layer. 2. That the intensity of the attack of water upon glass is influenced by atmospheric conditions. 3. The relative intensity of the attack by hot or by cold water varies with different kinds of glass. 4. That treating glass vessels of medium quality with water to increase their superficial power of resistance is of great utility; this is not the case by a long way with inferior

kinds of glass. 5. Glass surfaces have the property of absorbing alkali from solutions, and of retaining it when rinsed with water, so that prolonged contact with water is necessary to remove the alkali from the glass again.

—D. A. L.

A Porcelain Water-Bath. W. Dittmar. Chem. Zeit. 1891, 15, 1467.

ON account of the ease with which copper water-baths are attacked by acid vapours, and also on account of the difficulty of keeping such water-baths in a presentable condition, porcelain has been tried as a substitute for copper, but the water-baths have now disappeared by reason, it is said, of great liability to breakage. The author has, however, successfully used for some time water-baths of porcelain, to which is fitted an apparatus for keeping the water in the bath at constant height; by such means liability to cracking is overcome to a very considerable extent.

As a considerable improvement the author suggests the attachment of a ledge to the bath; on this ledge a thin glass globe may be placed fitting into a groove; on the globe is placed a circular piece of thick filter paper; the globe is cooled by the aid of a stream of cold water. By this means evaporation is performed in absence of air and dust.

INORGANIC CHEMISTRY.—
QUANTITATIVE.

Electrolytic Separation of Mercury from Copper. E. F. Smith and A. W. McCauley. Ber. 1891, 24, 2936–2938.

This separation was attempted previously (J. Franklin Inst. April 1889) but was not complete unless the amount of copper present in solution did not amount to more than 20 per cent. of the mercury present in solution. It has now been ascertained that, by careful regulation of current, it is not only possible to separate the two metals, when present in equal quantities, but also even when there is twice as much copper present as mercury.

A table given shows the results obtained.—T. L. B.

On a Colour Test of Kaolin and Sand. E. Nickel. Chem. Zeit. 1891, 15, 1125–1126.

See under VIII., page 162.

Analysis of Galena and Lead Sulphate. R. Benedikt. Chem. Zeit. 1891, 16, 43–44.

THE author converts the galena into the nitrate with the help of hydriodic acid. The galena, very finely powdered, is weighed into a basin and covered with water; a few cc. of commercial hydriodic acid, sp. gr. 1.7, are then added. If the water is omitted the action may easily become too violent. The dish is warmed on a water-bath till solution is complete, when it is evaporated to dryness. The residue is treated with nitric acid diluted 5–7 times, and again warmed. When oxidation is complete, the solution is evaporated to dryness, moistened with dilute nitric acid and filtered, when the whole of the lead will be in solution as nitrate. With lead sulphate a great quantity of iodine becomes free and, owing to the action of this iodine on the sulphuric acid, sulphur is deposited on the sides of the glass. Should any iodine be seen in the residue after moistening

with nitric acid, all the acid must be driven off and a few cc. of alcohol added, and the mixture evaporated to dryness and again moistened with nitric acid, diluted and filtered. In order to prevent the separation of iodine and sulphur, the author recommends the use of water containing a small quantity of red phosphorus, which will reduce the iodine to hydriodic acid, and be itself oxidised to phosphoric acid.

A complicated ore containing other metallic sulphides in addition to that of lead was analysed first in the usual way, and then by the method above described; in the former case 51.41 per cent. of lead was obtained, and in the latter 51.39.—E. C. C. B.

On the Determination of Small Quantities of Boric Acid.
F. Parmentier. *Compt. Rend.* 1891, **113**, 41–43.

The presence of small quantities of boric acid in mineral waters can easily be detected by means of the spectroscope. A drop of such water, rendered acid and placed in the non-luminous flame of a Bunsen burner, generally shows distinctly the characteristic bands of boron. The amount of boric acid present can be estimated roughly by the intensity of these bands.

The author has endeavoured to determine the quantity of boric acid present in such waters by a method depending on the two following facts:—(1.) Boric acid has no action upon helianthine which has been turned yellow by alkalis. (2.) Boric acid produces a characteristic change in the colour of tincture of sunflowers; this change occurs just when the acid forms a borate with the base present.

In carrying out the method it is essential that the solution should only contain salts which are without action upon tincture of sunflowers, such, for example, as salts of the alkalis or alkaline earths. Most of the mineral waters examined by the author contain calcium bicarbonate and often bicarbonate of iron. When evaporated down they produce precipitates which are insoluble in water and contain all the boric acid (as well as silica, arsenic, and phosphoric acid). The precipitate is treated with hydrochloric acid and evaporated down at a low temperature; it is then heated to 100° (to render the silica insoluble), and afterwards treated with a slightly alkaline solution of ammonium nitrate. The boric acid remains in solution; the residue contains the iron, manganese, arsenic, alumina, and phosphoric acid. The solution is acidified with sulphuric or hydrochloric acid and divided into two parts. In one of these the acidity is determined by means of a titrated solution of soda, using helianthine as an indicator; in the other the acidity is determined with tincture of sunflowers as an indicator. From the difference between the results the quantity of boric acid present can be deduced.

The author has made up artificial mineral waters with salts free from boric acid, and has then added known quantities of boric acid to them. By applying the above method to these he has convinced himself that it is accurate and reliable.—D. E. J.

A New Method of Determining Nitric Nitrogen, and also Total Nitrogen. E. Boyer. *Compt. Rend.* 1891, **113**, 503–505.

This method is based on the fact that when a nitrate is heated with a mixture of sulphur (1 part), calcium oxalate (2 parts), and soda-lime (6 parts), the whole of its nitrogen becomes eliminated in the form of ammonia. Nitrogen, if present in the form of ammoniacal or of organic compounds, is also liberated in the form of ammonia. A combustion tube, closed at one end, is charged as follows:—(1) with 2 grms. of calcium oxalate, (2) 10 grms. of soda-lime, (3) 10 grms. of above reducing mixture, (4) the substance, 0.5 grms. to be tested, intimately mixed with 50 grms. of the reducing mixture, (5) 10 grms. of the reducing mixture, (6) 10 grms. of soda-lime held in position by a plug of asbestos. The tube is heated in the usual way and the ammonia collected in standardised sulphuric acid.

—A. K. M.

Analysis of Chrome Iron Ore. C. Häussermann. *Chem. Zeit.* 1891, **15**, 1601.

The moisture is determined by heating the finely-powdered substance at 100° C., and then 0.5 gm. is mixed with 4 grms. of a mixture consisting of three parts of potassium carbonate to one part of caustic soda. The whole is first heated in a covered platinum crucible over a small Bunsen flame for two hours, after which the fusion is completed over the blow-pipe, the lid of the crucible being removed. After cooling, crucible and contents are boiled with water in a deep porcelain dish; the solution so obtained is acidified with sulphuric acid, and made up to a litre. Should a sandy powder remain in the dish, it is evident that the material has been insufficiently powdered, and a fresh start is necessary. The solution having been satisfactorily obtained, titration with ferrous ammonium sulphate is performed, the strength of the ferrous ammonium sulphate solution having been previously standardised against pure potassium bichromate.—T. L. B.

ORGANIC CHEMISTRY.—QUALITATIVE.

The Use of Ammonium Sulpho-Selenite as a Test for Alkaloids. A. J. Ferreira da Silva. *Jour. Pharm. Chim.* 1891, **24**, 102.

LAFFON, in 1885, described the use of a solution of 1 part of ammonium selenite in 20 parts concentrated sulphuric acid as a reagent for morphia and iodine. The reagent is also useful with the following:—

- Aconitine. After 20 minutes a light rose colour.
- Berberine. Greenish yellow, afterwards brown; the edges of the solution appear red, the middle violet; after half an hour a wine-red colour appears which remains after three hours.
- Brucine. A red changing to orange.
- Caffeine and cocaine. After three hours the solution is reddish.
- Curarine. Light violet changing to red.
- Delphine. Light red changing to violet.
- Digitaline. Yellow changing to a red precipitate.
- Eserine. Citron yellow changing to orange.
- Morphine. Greenish blue changing through violet to red.
- Narcein. First yellowish green, then brown and then red.
- Narcotine. Blue changing through violet into red.
- Papaverine. Blue changing through bottle green, greenish yellow, and bluish violet to red.
- Solanine. Green, afterwards brown.
- Senegine. Dirty yellow changing to red.
- Veratrine. Yellowish colour; after three hours a red precipitate settles.
- Atropine, cinchonidine, cinchonine, and pilocarpine give no reaction.—A. L. S.

ORGANIC CHEMISTRY.—QUANTITATIVE

A Rapid Method of Determining the Composition of Lubricating Oils. H. Gripper. *Chem. News*, 1892, **65**, 27–28.

The author describes a method for ascertaining the composition of lubricating oils containing both fatty and mineral oils, which is stated to be quicker than the usual process of saponifying the fatty oils, and shaking out the unsaponifiable matter with an immiscible volatile solvent. 2.5 grms. of the sample are saponified with 25 cc. of alcoholic potash of one-third or one-half normal strength, according to the amount of fatty oil supposed to be present, and the excess of alkali titrated with seminormal hydrochloric acid, using phenolphthalein as an indicator, a blank experiment for the determination of the strength of the alkali being performed at the same time. The oils most used for mixing with mineral oils for making lubricants are blown cotton-seed oil with a saponification equivalent

of 252, blown rape oil 280, neatsfoot 300, lard oil and tallow oil 290, and castor oil 313. The amount of potash, therefore, required for the saponification of these oils varies from 17.90—22.27 per cent. Taking the mean of these figures (20.08 per cent.) it may be assumed that one part of caustic potash will saponify 4.98 parts of the oil, from which the percentage of saponifiable oil may be readily calculated. The method is simply an application of the Koettstorfer process, and its degree of exactitude depends on the saponification equivalent of the saponifiable oil present in the sample being approximately equal to the mean value taken. The analysis is completed by filtering off the mineral oil from the neutralised soap solution, and taking its specific gravity by Hager's method, which consists in ascertaining the specific gravity of a mixture of alcohol and water in which a globule of the oil will float or sink indifferently. From the specific gravity of the mineral oil and that of the original mixture, the specific gravity of the fatty oil can be calculated. The method, without pretending to be exact, is adapted for technical purposes where great rapidity is important.

The following table shows how the results compare with those obtained by the usual method:—

	By Titration.		By Separation and Weighing.	
	Per Cent.	Specific Gravity.	Per Cent.	Specific Gravity.
I. { Hydrocarbon oil	78.3	0.891		
Saponifiable oil	21.7	0.950		
II. { Hydrocarbon oil	79.4	0.891	79.3	0.890

—B. B.

Hüb's Iodine Test for Fats. W. Fahrion. Chem. Zeit. 1891, 15, 1791—1792.

RESULTS obtained by Hüb's method or even by Holde's (this Journal, 1891, 954) are unsatisfactory, owing to the instability of the iodine-mercury solution. The author has been in the habit of retaining the mercuric chloride and the iodine solutions separate, adding first the former and then the latter to the chloroform solutions of the fat, but even then alterations take place, as the results tabulated below show; in these tests 25 grms. of iodine and 30 grms. of mercuric chloride were each dissolved in 500 cc. of strong alcohol, 250 cc. of each of these solutions were kept separate, whilst the other two halves were mixed. After the

periods noted 20 cc. of the latter and mixtures of 10 cc. of each of the former solutions were treated with potassium iodide and water and titrated with thiosulphate.

	20 cc.		10 + 10 cc.	
	Active Iodine.	Decrease.	Active Iodine.	Decrease.
Series I.: Immediately after preparation.	Grms. 0.4944	Per Cent. ..	Grms. 0.5068	Per Cent. ..
After eight days	0.3776	23.6	0.4882	3.7
After fourteen days	0.3404	31.2	0.4782	5.6
After five weeks	0.2500	49.6	0.4307	15.0
Series II.: Immediately after preparation.	0.4806	..	0.4987	..
After eight days	0.3961	17.6	0.4819	3.4
After fourteen days	0.3541	26.3	0.4733	4.3
After seven weeks	0.2397	50.1	0.4397	11.8

The irregularity is probably due chiefly to variations of temperature, hence it is advisable to keep such solutions at as low and as constant a temperature as possible. The author agrees with E. Pfleger in regarding the use of starch as an indicator not alone as superfluous but even as pernicious, and applies this method in the following manner both to drying and non-drying oils. The solutions he employs are—(1.) 65 grms. of mercuric chloride in 1 litre of 95 per cent. alcohol. (2.) 50 grms. of iodine in 1 litre of 95 per cent. alcohol. (3.) 25 grms. of crystalline sodium thiosulphate in 1 litre of water. (4.) 3.874 grms. of purest dry potassium dichromate in 1 litre of water. (5.) 100 grms. potassium iodide in 1 litre of water. (6.) Chloroform. The strength of the thiosulphate is first ascertained by mixing in a stoppered bottle 10 cc. of the potassium iodide, 5 cc. of ordinary dilute hydrochloric acid, 20 cc. of potassium dichromate, and 150 cc. of water, and titrating to a pale blue-green colouration with the thiosulphate, the number obtained = 0.2 grm. of iodine; the solution will remain constant for a long time if kept in a well stoppered bottle. The strength of the iodine solution is then tested by mixing, in a stoppered bottle, 10 cc. of mercuric chloride, 10 cc. of iodine solution, then 20 cc. of potassium iodide and 150 cc. of water, and titration with the thiosulphate to colourlessness, agitating vigorously. For the actual test, 0.2 to 0.3 grm. of the oil dissolved in 20 cc. chloroform is mixed with an amount of iodine solution corresponding to four times the quantity of iodine actually required for the absorption, and with an equal volume of the mercuric chloride solution, then after two hours for each grm. of iodine taken, about 4 grms. of potassium iodide, in the above solution, and 50 to 100 cc. of water are added, and the titration with thiosulphate to colourlessness proceeded with. A blank experiment should be carried out at the same time.—D. A. L.

Estimation of Cholesterolin. K. Obermüller. Zeit. f. physiol. Chem. 1891, 16, 143.

THE author has applied A. Kossel's method of saponification to the estimation of cholesterolin in the following manner:—1 grm. of fat containing the cholesterolin is dissolved in ether (using sufficient quantity to keep the soap magma subsequently formed thin enough, generally about 80 cc.), sodium ethylate (prepared by dissolving, with the aid of heat, 0.15 grm. of sodium in as little 90 per cent. alcohol as possible—1 to 1½ cc.) is added, and on shaking energetic saponification ensues and is complete in three hours at the ordinary temperature. The soap is filtered off and washed with ether; the latter, as well as any alcohol and water, are expelled from the filtrate, the dry residue redissolved in a minimum quantity of absolute alcohol, and the cholesterolin obtained from this solution by evaporation is dried at 120° and weighed. Solid fats yield granular soaps, fats rich in

oleic acid give stringy soaps. The method only answers for the former; for the latter the first part of the method is the same, but the treatment of the residue is different. It is dissolved in carbon bisulphide and is treated with a solution of bromine in carbon bisulphide of known strength, until a yellowish-red colouration is obtained.

The action of bromine on substances analogous to cholesterol is not known, but the author finds that isocholesterin absorbs 2 mols. of bromine.—D. A. L.

The Optical Determination of Albumen in Urine. H. O. G. Ellinger. *Jour. prakt. Chem.* 1891, **44**, 256.

THE oleorefractometer of Amagat and Jean is used for this purpose. The albumen is removed from one portion of the urine by boiling with a little acetic acid; the filtrate is made up to its original volume and placed in the outer spaces of the prism. The untreated urine is placed in the interior prism of the instrument. The displacement of the sought point is proportional to the amount of albumen present. Five determinations gave readings of $2\frac{1}{2}$, 4, $4\frac{1}{2}$, 5, 5. By weighing the albumen the absolute amounts were found to be respectively 2.71, 4.36, 4.94, 5.10, 5.22 parts per thousand.

—A. L. S.

Choline as a Constituent of Beer. J. Kjedahl. *Meddelelser fra Carlsberg Laboratoriet*, 1891, **3**, 79.

IF a large excess of a solution of iodine in potassium iodide be added to beer or wort, tinct, beetle-green needles appear after a short time; these are a polyiodide of choline. To obtain choline from wort, the latter is evaporated to one-half and treated with excess of milk of lime and one or two volumes of alcohol. The filtrate is acidified with sulphuric acid, evaporated on the water-bath with excess of barium carbonate, until all the alcohol is volatilised and then after distillation the polyiodide of choline is precipitated by iodide solution. The polyiodide is decomposed by sulphurous acid, the solution filtered, the iodine replaced by chlorine by shaking with silver chloride and the solution evaporated; by treatment with platinum chloride the platinum double salt is prepared.

Several determinations of the amount of choline in beer and wort showed that the amount was the same before and after fermentation.

Besides free choline, beer also contains a choline compound, perhaps lecithin.—A. L. S.

Testing Paper for Wood Fibre. F. v. Hühnel. *Centr. Org. f. Waarenkunde u. Techn.* 1891, **1**, 219.

IT is pointed out that various carbohydrates, such as cane-sugar, dextrins, &c., give reactions resembling the lignin reactions, for instance:—Swedish filter paper, prepared from pure cellulose, impregnated with cane-sugar solution and tested with phloroglucol and hydrochloric acid at first gave no reaction, but when dry it becomes distinctly red just as if wood fibre were present. Again wood cellulose, which tested in the ordinary way with phloroglucol and hydrochloric acid, showed only traces of lignin, became intensely red when, after treatment with the reagents, it was washed slightly and then quickly dried at 100° – 110° . The author, therefore, considers it advisable, whenever drying or heating has taken place during a test of this kind, to supplement the observation by a careful microscopical examination for the sake of confirmation.—D. A. L.

ANALYTICAL AND SCIENTIFIC NOTES.

On an Explosive Compound formed by the Action of Baryta-Water upon Chromic Acid in presence of Oxygenated Water.

See under XXII., page 180.

New Books.

MANUAL OF CHEMICAL TECHNOLOGY. By RUDOLF VON WAGNER. Translated and edited by WILLIAM CROOKES, F.R.S. From the 13th enlarged German edition as remodelled by Dr. Ferdinand Fischer; with 596 Illustrations. 1892. London: J. and A. Churchill, 11, New Burlington Street.

LARGE octavo volume, bound in cloth. Contains Preface by F. Fischer (translated), Preface to the English Edition by William Crookes, Table of Contents, subject-matter covering 948 pages, an Appendix of 4 pages, and an Alphabetical Index. The subjects treated of in the volume are as follows:—

Section I. Technology of Fuel. *Section II.* Metallurgy. *Section III.* CHEMICAL MANUFACTURING INDUSTRY, including the following branches:—Water and Ice. Artificial Mineral Waters. Sulphur. Sulphuric Acid. Potassium Salts, Common Salt, and Salt Works. Soda. Chlorine, Chloride of Lime and Chlorates. Bromine. Iodine. Nitric Acid and Nitrates. Explosives. Ammonia. Phosphorus. Matches. Phosphates, Manure. Boric Acid and Borax. Salts of Aluminium. Ultramarine. Compounds of Tin and Antimony, of Arsenic, of Gold, Silver, and Mercury, of Copper, of Zinc and Cadmium, of Lead, of Manganese and Chromium, Iron Compounds including Ferrocyanogen. Inorganic Pigments, Thermo-chemistry. *Section IV.* THE ORGANIC CHEMICAL MANUFACTURES. Alcohols and Ethers. Organic Acids. Treatment of Coal-tar. Organic Colouring Matters. Tar Colours. Benzene Colours. *Section V.* Glass, Earthenware, Cement and Mortar. *Section VI.* Articles of Food and Consumption. *Section VII.* Chemical Technology of Fibres. *Section VIII.* Miscellaneous Organic-Chemical Arts and Manufactures. Appendix containing a set of useful Tables. The price of the volume is 1*l.* 12*s.*

THE PHOSPHATES OF AMERICA. Where and How they Occur; How they are Mined; and What they Cost. With Practical Treatises on the Manufacture of Sulphuric Acid, Acid Phosphate, Phosphoric Acid, and Concentrated Superphosphates. Also, Selected Methods of Chemical Analysis. By FRANCIS WYATT, Ph.D. Second Edition. 1891. New York: The Scientific Publishing Co., 27, Park Street. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS work is dedicated to R. P. Rothwell, the editor of the *Engineering and Mining Journal*, by the author, and is an 8vo volume, bound in cloth, and containing Prefaces to first and second editions, 178 pages of subject-matter, and an Alphabetical Index.

CHAP. I. Introductory. II. Phosphates and their Assimilability. III. The Phosphates of North America. IV. The Phosphate Deposits of South Carolina. V. The Phosphate Deposits of Florida. VI. Sulphuric Acid Manufacture. Under this heading occurs the following sentence on the subject of chamber construction:—"The subject of chamber construction is well worn, if not exhausted; their form and size have long been bones of contention over which certain viscerates, with plenty of time for useless discussion, have growled *ad nauseam*." As to thickness of lead to be employed, the author says, "A happy medium may be attained by adopting seven-pound lead for the first chamber and six-pound lead for the second." On the dimensions, he says, "The amount of chamber room should in no case be less than 20 cubic feet for every pound of sulphur consumed." Speaking of the Glover Tower, the author says, "This remarkably ingenious and valuable addition to the sulphuric acid plant is named after its disinterested inventor, Mr. John Glover, an English chemist." VII. Manufacture of Superphosphate, Phosphoric Acid, and High-Grade Supers. VIII. Selected Methods of Phosphate Analysis and Generally Useful Laboratory Details. On the subject of divergent analyses, &c., the author asks, "Why should there be any material difference between the shippers' and buyers' samples, if both are faithfully taken according to prescribed rules and

with proper regard for the true interests of each party to the contract?" There follows later a short chapter on SAMPLING, and minute details are given. This very properly precedes any details given as to Analysis. After a full description of the Analytical Methods, the work concludes with a "Table showing the principal Apparatus and Chemicals comprising the Outfit required in Phosphate Mining or Fertiliser Factory Laboratories." The work is illustrated by means of 20 well executed wood engravings, two maps, and 20 photographs. The price of the book is 4 dols., or, approximately, 18s. in English money.

SYSTEMATIC MINERALOGY, based on a natural classification, with a General Introduction. By THOMAS STERRY HUNT, M.A., LL.D. 1891. New York: The Scientific Publishing Co., 27, Park Place. London: H. Grevel and Co., 33, King Street, Covent Garden.

This work is dedicated to his friend James Douglas, the metallurgist. It is a large 8vo. volume, bound in cloth, and containing Table of Contents, Preface, 376 pages of subject-matter, and the Alphabetical Index. The text is subdivided into Chapters, as follows:—Chapter I. The Relations of Mineralogy. II. Mineralogical Systems. These are divided as involving the Natural History and Chemical Methods, and the possibility is considered of reconciling the two. III. First Principles in Chemistry. IV. Chemical Elements and Notation. V. Specific Gravity. VI. The Coefficient of Mineral Condensation. The views on this problem of Gibbs, Roscoe, Victor Meyer, Louis Henry, &c. are given. VII. The Theory of Solution. VIII. The Relations of Condensation to Hardness and Insolubility. IX. Crystallisation and its Relations. X. The Constitution of Mineral Species. XI. A New Mineralogical Classification. XII. Mineralogical Nomenclature. XIII. Synopsis of Mineral Species. XIV. The Metallaceous Class. XV. The Itallidaceous Class. XVI. The Oxydaceous Class. XVII. The Pericaustaceous Class. XVIII. Mineral History of Waters. XIX. There then follows:—(1.) A General Alphabetical Index, and (2.) An Alphabetical Index of Mineral Names. The price of the book is 5 dollars, or approximately 11. 2s. 6d.

CHEMISTRY OF THE CARBON COMPOUNDS OR ORGANIC CHEMISTRY. By Professor V. VON RICHTER. Authorised Translation by Edgar F. Smith, Professor of Chemistry, University of Pennsylvania. Second American Edition from the Sixth German Edition. 1891. London: Kegan, Paul, Trench, Trübner & Co., Limited.

This well-known work on Organic Chemistry, according to the preface of the translator, is as well received in America as it is in England. The present volume is an 8vo., bound in cloth, and after Prefaces and Table of Contents, commencing with an Introductory Chapter on General Theory, Methods of Analysis, Vapour Density Determination, &c. The special part of the work with Introductory included, occupies 1016 pages, and an Alphabetical Index completes the work. The eight or nine illustrations are exceedingly well executed wood engravings.

The special part is subdivided as follows:—

Class I.—FATTY BODIES OF METHANE DERIVATIVES.

Hydrocarbons. Alcohols, Acids and their Derivatives.

Monovalent Compounds. Alcohols. Unsaturated Alcohols. Ethers. Mercaptans and Thio-ethers. Esters of Mineral Acids. Amines. Hydrazines. Phosphines. Arsenic Bases. Metallo-organic Compounds. Aldehydes and Ketones. Monobasic Acids. Cyanogen Compounds. *Divalent Compounds.* *Trivalent Compounds.* *Tetravalent Compounds.* *Pentavalent Compounds.* *Hexavalent Compounds.* Carbohydrates. Tetramethylene Derivatives, &c. Furfuran Group. Thiophene Group. Pyrrol Group.

Class II.—BENZENE DERIVATIVES. Hydrocarbons, &c. *Diazo-Compounds.* *Azo-Compounds.* *Hydrazine Compounds.* Sulpho-compounds of the Hydrocarbons. Phenols. Dihydric Phenols. Trihydric Phenols. Quinones. Alcohols. Divalent Alcohols. Aldehydes. Ketones. Ketone-aldehydes. Di-ketones. Nitriles. AROMATIC ACIDS. Ketonic Acids. Dibasic Acids. Tribasic Acids. Tetrabasic Acids. Hexabasic Acids. Unsaturated Compounds.

Derivatives with Closed Side Chains. (1.) *Derivatives of Directly Combined Nuclei.* (2.) *Derivatives of Benzene Nuclei joined by one Carbon Atom.* (3.) *Derivatives of Benzene Nuclei joined by two Carbon Atoms.* (4.) *With Condensed Benzene Nuclei.*

Derivatives of Nuclei Containing Nitrogen. (1.) Derivatives of five-membered Nuclei. (2.) Quinoline Group. Isoquinoline Group. Benzodiazines. Cinnolines. Quinazolines. Quinoxalines. Acridine Group. Phenazine Group. Safranines. Alkaloids. Terpenes. Camphor. Resins.

The price of the work is 20s.

THE CHEMISTRY OF PAINTS AND PAINTING. By A. H. CHURCH, M.A., F.R.S., Professor of Chemistry in the Royal Academy of Arts, London. Second Edition. Revised and enlarged. 1892. London: Seeley and Co., Limited, Essex Street, Strand.

This book is dedicated to Sir Frederick Leighton by the author. It is of 8vo. size and handsomely bound in green cloth, and gilt. There are Prefaces to First and Second Editions, a Table of Bibliographical Notes of Works consulted or recommended for consultation. Then follow Table of Contents, 320 pages of subject-matter, and the Alphabetical Index. The text is subdivided as follows:—Introduction. PART I. PAINTING GROUNDS. Paper, Vellum, Ivory, Plaster or Intonaco, Stone, Panel, Canvas. PART II. VEHICLES AND VARNISHES. Oils, Resins, Waxes, Paraffin Wax. Yolk and White of Egg, Size, Glue. Gums, Glycerin, Honey. Water-glass, Lime- and Baryta-water. Solvents and Diluents. Siccatives or Dryers. Varnishes and Oleo-resinous Vehicles. PART III. PIGMENTS. White, Yellow, Red, Green, Blue, Brown, Black Pigments. Classification of Pigments. Tables of Permanent and Fugitive Pigments. Selected and Restricted Palettes. PART IV. PAINTING. Methods. Study of Old Paintings. Conservation of Pictures and Drawings. Trials of Pigments. The price of the book is 5s.

TECHNISCH-CHEMISCHES JAHRBUCH, 1890—1891. Ein Bericht über die Fortschritte auf dem Gebiete der chemischen Technologie vom April 1890 bis April 1891. Herausgegeben von Dr. RUDOLF BIEDERMANN. Dreizehnter Jahrgang. Mit 263 in den Text gedruckten Illustrationen. 1892. Berlin: Carl Heymann's Verlag. London: H. Grevel and Co., 33, King Street, Covent Garden.

OCTAVO volume, strongly bound in cloth and gilt-lettered. It commences with a brief Preface, followed by Tables of Contents and Errata, and List of Works consulted and referred to in the text, with the Abbreviations used. The subject-matter covers 573 pages, and the work contains 263 well-executed wood engravings. The classified list of New Books published during the year is an interesting feature, and it immediately precedes the Alphabetical Index, which comprises an index of authors and one of subject-matter.

The matters treated of in the text are as follows:—I. Patent Laws. II. Iron and Steel. III. The Alkali Metals, Magnesium, Aluminium. IV. Gold and Silver. V. Copper. VI. Lead. VII. Zinc. VIII. Tin. IX. Nickel and Cobalt. X. Chromium and Manganese. XI. Bismuth, Arsenic, Antimony, Mercury. XII. Chlorine, Hydrochloric Acid. XIII. Sulphur, Sulphurous Acid, Sulphuric Acid. XIV. Hydrogen, Oxygen, Carbonic Acid. XV. Soda. XVI. Potash Salts. XVII. Ammonia. XVIII. Alkaline Earths. XIX. Aluminium Compounds. XX. Glass. XXI. Earthenware. XXII. Cement. XXIII. Artificial Stone. XXIV. Explosives. XXV. Illuminants. XXVI. Fuel. XXVII. Sugar. XXVIII. Starch and Starch Sugar. XXIX. Wine. XXX. Beer. XXXI. Spirits. XXXII. Fats, Soaps, &c. XXXIII. Water. XXXIV. Foodstuffs. XXXV. Mannes. XXXVI. Tanning. XXXVII. Organic Acids. XXXVIII. Alkaloids. XXXIX. Colouring Matters. XL. Textile Fibres and their Treatment. XLI. Paper. XLII. Photography. XLIII. Apparatus and Machinery. The price of the book is 12s.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade and other Journals.)

RUSSIA.

Classification of Articles in Customs Tariff.

Note.—Pond = 36 lb. avoirdupois. Rouble = 100 copecks = 3s. 2d.

The following decisions affecting the classification of articles in the Russian Customs tariff have recently been given by the Russian Customs authorities:—

Ethers or fruit essences employed for flavouring sweets and in medicine though with an admixture of spirits and with not less than 75 per cent. of ether, under sect. 115. Duty, 10 roubles gold per pound; the same ethers mixed with spirits containing less than 65 per cent. of ether under sect. 27, as spirits with flavouring admixtures. Duty, 12 r. gold per pond, gross; when imported in casks and barrels and when imported in bottles of $\frac{1}{2}$ of a vedro, 1 r. gold per bottle.

NEW CUSTOMS TARIFF OF MEXICO.

Note.—Kilog. = 2·204 lb. avoirdupois. Peso = 4s. 2d.

The following is a statement of the rates of import duty on chemicals now levied under the new Customs tariff of Mexico, which came into operation on the 1st November last:—

Note.—By "net weight" must be understood the actual weight of the merchandise; by "legal weight," that which includes besides the "net weight" that of the interior bottles, boxes, winders, wrappers, &c. in which the articles are imported, and by "gross weight" the total weight of the packages. When merchandise which pays according to the "legal weight" has no other covering besides the one which forms the outside package, the actual weight of the merchandise will be considered to be its legal weight.

EXTRACTS FROM DIPLOMATIC AND
CONSULAR REPORTS.

SPANISH COLONIES.

Perfumery Imports.

THE imports of perfumery articles and soaps into Cuba are very large; but this country does not appear to possess any appreciable share in them. Florida water comes from the United States, some very common perfumes from Germany, and low grades of soap are manufactured locally. But all these sources are as nothing compared with the enormous import of French goods, especially of the finer qualities. Fine French toilet-soap, oils, scents, powders, &c., are exceedingly popular. Certain Paris perfumery houses are said to export 500,000 francs' worth of perfumery to Cuba every year. Against this trade English and American houses have hitherto tried to compete in vain. But there are now some German firms who send travellers through Cuba every year, and, it appears, have met with some success.

Drugs for Porto Rico.

In his review of the trade of the Spanish West Indian colony of Porto Rico in 1890, Consul Latimer observes that drugs and chemicals to the amount of 71 tons, valued at 15,320*l.*, have come from the United States, France, Spain, England, and Germany. Not embraced in the foregoing heading, there has been a supply of 2,311 tons of nitric, muriatic, and sulphuric acid, of the value of 32,397*l.*, 2,128 tons of which come from Spain, while England sends but 38 tons. Of the total import of soap of 2,250 tons, valued at 58,565*l.*, Spain furnished 2,228 tons, and England and Cuba the remainder.—*Chemist and Druggist.*

GENERAL TRADE NOTES.

MANCHESTER CHAMBER OF COMMERCE.

The Chemical Sectional Committee of the Manchester Chamber of Commerce has had under its consideration a communication received from Her Majesty's Consul-General at Christiania with reference to coloured cotton goods shipped from this country to Norway. These goods were alleged to contain arsenic, and in consequence of this it was stated that injury was done to British traders, as the Government of Norway did not permit the import of goods containing arsenical compounds. The secretary of the Chamber was requested to procure samples of the goods complained of. Fifteen samples were in due time received, and a special committee, appointed to examine them, report that in at least 12 samples an excessive quantity of arsenic was found, and that three contained only traces of it. The opinion was also expressed that the employment of arsenic or arsenical compounds could be dispensed with by dyers and printers. The attention of the committee was also called to the prosecution, on the part of the Corporation, of certain chemical manufacturers for the emission of black smoke. The committee are of opinion that there are a number of bye-laws now in existence which, if enforced, would injuriously affect a large number of manufacturers, without in the least degree benefiting the general public. These bye-laws (they say) may be admirable for most purposes, but some at least are impracticable when applied to the chemical and allied trades. The difficulties which British manufacturers of fine chemicals, chemical and medicinal preparations, colours, dyes, &c., experience in competing with foreign nations—especially Germany and Switzerland—are already serious enough without being unnecessarily increased. In the opinion of the committee, too little importance is yet attached by traders and manufacturers generally to the development of our chemical industries, and the result of this apathy is clearly shown by comparing the progress by leaps and bounds made yearly by

Germany and other countries with the almost stationary condition of these industries in this country. This want of progressiveness is due to inferior technical education of the highest grade, to the unfairness of our Patent Laws in regard to foreign patentees, and to the needless exactions of some of the bye-laws of the local authorities. These tend seriously to increase the expenditure on plant without reason, and without advantage to the public at large.—*Ibid.*

THE METRIC SYSTEM IN CHINA AND JAPAN.

The Secretary of the Decimal Association writes, with reference to the recent adoption of metric weights and measures in Japan, that the military authorities of that country now prefer to place their orders in France or Germany rather than in England, because the metric measures are followed in those countries. The secretary further states that a recommendation is about to go forward from a high authority in China, to whose views attention is usually paid, that China should adopt, as Japan has already done, the metric system of weights and measures. Unless the importance of this statement is fully realised, there may be a loss of valuable business to English firms; for, in countries where the metric system is used, the Government naturally prefer to buy the foreign goods required from countries where the same weights and measures are followed.—*Ibid.*

PHOSPHATES IN 1891.

Report by the Anglo-Continental (late Ohlendorff's) Guano Works.

We beg to append table giving the quantities and origin of the phosphates imported into the United Kingdom during the last five years.

There has been a serious falling off in the quantities imported, amounting to 86,729 tons, as compared with 1890, and to 48,181 tons as compared with 1889.

Already during the first half-year we reported a reduction in the importations, and the decrease has continued to the end of the year, and seems to have been spread over all the important ports alike.

The deficiency is probably due not only to a smaller demand for phosphatic manures, but also to the heavy stocks left over from the previous year, when importations were evidently in excess of requirements.

In consequence of the interruption of production on the Coosaw river the quantities received from South Carolina were only 97,000 tons, but the shortage was partly made good by the supply from Peace river and other Florida phosphate mines. This pebble phosphate from Peace river has found ready buyers as it is even preferred to Bull river phosphate.

A considerable change has taken place in our supply of high-class phosphates containing 70 per cent. of phosphate of lime and over. Only about 16,000 tons of phosphates arrived from Aruba and Sombreno last year, against respectively 16,000 and 19,000 tons in 1889 and 1890.

The supply from Florida was 35,203 tons, of which about 16,000 tons were river phosphates from Peace river and one cargo from Alafia river. Part of the high-grade phosphate from Florida was reshipped to the Continent, like most of the Canadian phosphate which arrives in this country.

The consumption of high-grade phosphates in the United Kingdom will therefore not have exceeded about 50,000 tons last year.

Considerably less Somme and Belgian phosphates have been used, especially if we consider that in the quantity of phosphates from Belgium, a large quantity of Osso phosphate from the new mines near Liège is included.

Although the production on the Coosaw river was interrupted last year it appears that South Carolina produced more phosphate than ever, the consumption in the United States evidently increasing rapidly.

The following are the figures of the last three years :—

	Tons.
1889.....	462,101
1890.....	537,149
1891 (about).....	600,000

During 1889-90, from September 1 to August 31 —

Tons.
219,812 were shipped to Europe from Charleston and Beaufort.
250,936 were sent inland by rail and coastwise.
116,000 were consumed locally.
<u>586,758</u>

showing that whilst about 220,000 tons, mostly river phosphates, are sent from South Carolina to Europe, the remainder is consumed in the United States.

The production in Florida last year began to assume large proportions.

Calculated at the present rate of production Florida would furnish about 100,000 tons of river (pebble) phosphates and about 100,000 tons of high-class land rock with perhaps some low-class phosphates for home consumption.

It is, however, impossible to estimate future production with any degree of certainty, because the mines inland are only partially developed, and some are still waiting the completion of railway connexions, whilst other large mines work at reduced speed, or not at all, on account of the present low prices of phosphates in Europe.

The sanguine hopes of the many miners in Florida are not likely to be realised, because it costs more to raise saleable phosphates than they expected, and there is no possible sale for large quantities of high-class phosphates in Europe.

In the Somme district in France raisers of phosphates have suffered under the serious fall in prices, caused by the new discoveries in Florida, and the production last year was probably on a somewhat smaller scale than the previous year. As regards cost of raising, preparing for and bringing into the market, the Somme raisers are much better placed than any other miners; but many properties in the Somme were acquired at such a high cost that the present reduced prices must be very unremunerative to them.

We have not yet received exact figures of last year's production in France, but give the following figures for previous years :—

In 1889 the quantity of phosphates produced in the Somme was stated to have been about 260 000 tons, of which about 100,000 tons were of high grade, say 65—80 per cent.

In 1890 the production in the Somme has been stated as 250,000 tons, of which about 120,000 tons were exported.

The export of phosphates from France was—

	Tons.
1887.....	50,898
1888.....	99,673
1889.....	150,963
1890.....	122,002

During the past year (1891) the quantity of Somme phosphates exported from France must have been much smaller, as is evident from the quantities landed in the United Kingdom and Germany; but the home consumption in France seems to be increasing, and a large quantity of low-class ground phosphates is used by the French farmers direct without manufacture into superphosphate.

We have not yet been able to obtain particulars of the quantity of phosphate raised last year in Belgium, but it seems clear that the production of calcareous phosphate near Mons is not much increasing, whilst the old mines near Mons are about worked out. The new mines near Liège are in full activity, and although the quantity raised will be much less than expected, still the production will be important for some years to come.

Germany has always been the best market for high-class phosphates, and consequently the new Florida phosphate has been most extensively used in that country. We have particulars of imports during last year only from two ports, which of course are no indication of the total quantity used

in Germany, but are characteristic as to the origin of the material, and may be summarised as follows :—

	Tons.
South Carolina.....	13,022
Pence River (Florida).....	7,540
Florida land rock.....	20,455
Somme phosphates.....	5,803
Canadian.....	4,210
Aruba Curaçoa.....	870
	<u>52,000</u>

THE PRODUCTION OF QUICKSILVER IN CALIFORNIA.

The report of the Quicksilver Mining Company, of New Almaden, Cal., for the year ending December 31st, 1891, is the most unfavourable statement made by that company during the past 21 years. The production of quicksilver was smaller than in any preceding year, being but 68 per cent. as great as in 1890, while in value there was a still more important decline, the average price of quicksilver having been 12·06 dols. per flask lower in 1891 than in 1890.

In 1890, 22,649 tons of ore were roasted, and in 1891, 25,548 tons, but the average yield of the ore during the latter year was only 1·22 per cent., against 2·02 per cent.

in 1890. On the other hand the expenses in 1891 were very nearly as heavy as in 1890; the yield of quicksilver being so much less the cost of production rose from 33·87 dols. per flask to 48·62 dols., and for the first time in 21 years the mines were operated at a loss. The deficit amounted to 57,523·96 dols., which was 6·97 dols. per flask.

There seems no doubt that the New Almaden mines are now upon the verge of exhaustion, and that within a few years the quicksilver mining industry of California will be a thing of the past, notwithstanding the remarkably able and economical management of the mines. The production of the California mines reached its maximum in 1879, when 79,396 flasks were produced. Since that time the output has diminished steadily. In 1881 the yield was 60,851 flasks; in 1891 it had fallen to 22,904 flasks.

The quicksilver mines of California have had a glorious past and have returned large profits to their owners. From 1850 to 1891, both years inclusive, they produced 1,590,674 flasks, or 121,696,561 lb. of quicksilver valued at 71,508,021 dols. Of this amount the New Almaden mines, owned by the Quicksilver Mining Company, produced 924,659 flasks, or over 58 per cent. In 1881 the product of this company was 42·8 per cent. of the total, and in 1891, 36 per cent. With the approaching exhaustion of the California mines it would seem that we are likely to see higher prices of quicksilver this year. No figures have yet been compiled showing the world's production of quicksilver in 1891, but the output of the Almaden mines of Spain was probably about 47,500 flasks, against 50,035 flasks in 1890. The mines of Spain and California are the largest producers and turn out about 70 per cent. of the total amount of the world's quicksilver.—*Engineering and Mining Journal*.

BRITISH ALKALI IN THE STATES.

The American market for heavy chemicals has been brisk lately, owing, says the *O. P. and D. Reporter*, to the equalisation of freight rates from New York with those of Boston, and the probability of an early advance in ocean freights. The first reason has caused the divergence of some trade from Boston to New York, and the second has influenced buyers to place larger orders for early forward shipment than they probably would have done otherwise. So far as caustic soda is concerned the effect of the present conditions is likely to be transitory, and will not increase the figures representing the total volume of trade for the twelve months if the experiences of the past year are to be taken as a criterion. The statistics of exports of the heavy chemicals to the United States during 1891 are just to hand, and afford some interesting comparisons with those of the two preceding years. The shipments of bleaching powder are considerably larger than those of the previous year. On the other hand, the exports of caustic soda, sal soda, and salt cake show a decided falling off, which may be attributed in a large part to the increasing consumption of the domestic products.

The figures showing the shipments to the United States from England are as follows :—

	Tons.	1891.	1890.	1889.
Soda ash.....	68,684	67,168	62,769	
Bleach.....	49,303	45,781	42,608	
Caustic soda.....	31,355	37,423	32,875	
Sal soda.....	5,900	9,845	6,337	
Salt cake.....	8,059	8,535	7,343	

— *Chemist and Druggist*.

THE GLASS-BOTTLE TRADE IN GERMANY.

The German glass-bottle industry, says the annual report of one of the biggest bottle-making firms in the world (the Gerresheimer glassworks), has been in a rather bad way in 1891. Instead of a profit of 608,841 marks, such as

these works made in 1890, when they paid their shareholders 9 per cent., the net profit in 1891 has only been 295,512 marks, admitting of no larger dividend than 5 per cent. The output of bottles, however, increased from 47,660,000 in 1890 to 50,920,000 in 1891. Of the last-named number 29½ millions were sold to the German home trade, and 21½ millions for export. The prices realised declined considerably, the smaller output of 1890 selling for 3,510,000 marks and the larger one of 1891 for 3,460,000 marks. — *Ibid.*

DISCOVERY OF CALCIUM TUNGSTATE.

A discovery of economic importance has just been made by Mr. W. F. Ferrier, B.A. Sc., of the Canadian Geological Survey, in specimens collected some years ago. The specimens were procured from an opening made for gold on a quartz vein in the township of Marlow, Beauce county, province of Quebec, near the State of Maine boundary line. They are found to hold scheelite or calcium tungstate, of a yellowish-white colour, resembling blende so much as to be mistaken for the latter. It is the intention of the owners to develop the property. — *Engineering and Mining Journal.*

PAPERS OF INTEREST TO TECHNOLOGISTS.

The following articles in the *Board of Trade Journal* for February will repay perusal :—

“Prussian Mining and Metallurgical Industries,” p. 135.

“Regulations for the Carriage of Petroleum through the Suez Canal,” p. 163.

“New Customs Tariff of Argentina,” p. 177.

“The Industries of Orenbourg,” p. 198.

“German Sugar Industry, 1890—91,” p. 199.

“Fibre Industry in Queensland,” p. 219.

BOARD OF TRADE RETURNS

SUMMARY OF IMPORTS.

	Month ending 31st January	
	1891.	1892.
	£	£
Metals.....	1,715,867	1,822,503
Chemicals and dyestuffs.....	852,787	827,086
Oils.....	636,134	566,628
Raw materials for non-textile industries.	2,378,863	2,423,044
Total value of all imports	33,741,082	38,485,244

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

538. J. Arnold. Improvements in or connected with thermometers. January 11.

541. L. Ronmien. Improved filtering receptacle for substances from which oil or other liquid is to be expressed by hydraulic and other presses. January 11.

765. S. Fox. Improvements in furnaces for the application of water-gas for heating and welding purposes. January 14.

801. J. Pelat. Improvements in apparatus for use in filtering and purifying oils, glucose, or other like matters. January 14.

829. J. W. Hall. An improvement connected with gas-producer and other furnaces. January 15.

836. A. M. Strathern and A. G. Strathern. Improvements in and relating to apparatus for governing or regulating the pressure or flow of illuminating gas or other fluids. January 15.

845. H. E. Newton.—From R. N. Oakman, jun., United States. Improvements in gas furnaces. January 15.

1054. J. H. Bovenkerk, jun., and A. C. Kuyt. Improvements relating to softening water. January 19.

1172. A. T. Rapkin and F. Cossor. Improvements in or connected with thermometers. January 21.

1181. W. J. Lomax and C. J. Lomax. A combined refuse furnace and gas apparatus. January 21.

1210. B. Zeitschel. Improvements in apparatus for rapidly heating liquids. Complete Specification. January 21.

1738. W. P. Thompson.—From J. W. Meens, Belgium. See Class XVII.

1777. B. Bolton. Improved non-conducting composition or paint for steam-heated surfaces. January 29.

1858. W. L. Wise.—From C. d'Abbadie de Barran, Island of Mauritius. See Class XVI.

1863. J. G. Hall. See Class XVII.

1991. J. Wright. Improvements in apparatus for heating water and fluids of all kinds; also applicable to ammoniacal and other liquors for distillation for steam boilers or any other purpose. February 2.

2117. C. F. Betting. Improvements in assay or chemical balances. Complete Specification. February 3.

2363. W. P. Ingham and E. Crowe. Improvements in gas-fired recuperative kilns. February 8.

2516. J. A. Mays. A process and apparatus for effecting the concentration or separation of solids. February 9.

2790. J. W. Bowley. Apparatus for producing cold in or freezing liquids. February 12.

2895. F. M. Robertson, H. S. Fearon, and W. S. Miller. Improvements in the process of, and apparatus for, evaporating or drying. February 13.

1846. J. King. Apparatus for drying granular, pasty, or pulverulent materials, or for carbonising animal or vegetable substances, or for concentrating or evaporating liquids; and an improved furnace for heating air for the same and for other purposes. January 20.

5340. A. Dervanx. Method and apparatus for clarifying muddy liquids. February 10.

5529. J. S. Sawrey and H. Collet. Apparatus for separating liquids from solid matters suspended therein. January 27.

6159. J. Hardman and J. Peake. Retort charging devices. February 17.

6387. W. Heyes. Apparatus for concentrating acids and other liquids. February 17.

7188. M. Merichenski. Improvements in carburettors. February 3.

15,192. O. M. Row. Apparatus for condensing steam and other vapours, and for heating or cooling fluids. February 10.

19,464. E. Kerr. Improvements in furnaces. February 10.

21,248. W. Butlin. An improved tnyere. January 20.

1892.

11. E. C. Peck. Taps or cocks for liquids. February 17.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

535. G. M. S. Wilson. Improvements in the manufacture of gas. Complete Specification. January 11.

848. G. B. Field. Means for burning straw, cornstalks, and such like fuel. Complete Specification. Filed January 15. Date applied for August 11, 1891, being date of application in United States.

864. J. Ruscoe. Improvements in apparatus for charging gas retorts. January 15.

878. G. T. Beilby. Process of and apparatus for the manufacture of cyanides. January 16.

879. G. T. Beilby. Process and apparatus for obtaining cyanides. January 16.

927. W. B. Hartridge. Improvements in or connected with apparatus for washing or purifying smoke. January 16.

952. W. S. Chenall and W. F. S. Chenall. Improvements in solidifying animal, vegetable, and mineral oils, and volatile and inflammable fluids. Complete Specification. January 18.

964. C. Allina. Solidifying petroleum and the carbhydrates contained in same for facilitating transportation and use as fuel, also re-liquefying same. January 18.

965. W. E. Vickers and G. A. Everett. Improvements in machinery or apparatus for effecting the complete mixture of inflammable gas or vapour with air. Complete Specification. January 18.

1437. I. S. McDougall and J. T. McDougall. Improvements in the treatment of oils for rendering them capable of transport or storage, and of use as fuel, or as illuminants, with greater safety and convenience than hitherto. January 25.

1569. J. Tennant, J. Tennant, and W. R. Tennant. Improvements in candles. January 26.

1575. A. Klönne. Improvements in the manufacture of illuminating and heating gas, and in apparatus therefor. January 26.

1647. J. Mitchell. Improvements in coke ovens. January 27.

1804. S. Fox. Improvements in the manufacture or production of water-gas and apparatus therefor. January 29.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

1071. B. Corcoran. Mixing machine for amalgamating exact proportions of flours, chemicals, and other substances. January 20.

1805. T. W. Lee. Improvements in the manufacture or production and distribution of mixture of inflammable gas and air, and in apparatus therefor. January 29.

1958. W. Coultas, T. Siddell, and J. L. Smith. A novel or improved apparatus constituting a combined boiler and gas producer for the generation of steam and the production of gas, whether used in combination or for separate purposes. February 2.

1960. J. Isherwood. Improved apparatus for economising heat and fuel. February 2.

2073. W. H. Wilson. Improvements in and connected with the manufacture of illuminating gas. February 3.

2259. T. White. See Class IX.

2367. L. Sepulchre. Gas generator for the distillation of mineral oils and the combustion at a distance of a part or the whole of the products of the distillation applicable to apparatus for lighting and heating. Complete Specification. February 8.

2377. R. H. Courtney. Improvements in and means for increasing the illuminating power of candles and night and fancy lights; also in the holders to be used for same. February 8.

2434. J. Swallow and C. West. Improvements in artificial fuel. February 8.

2578. W. L. Malcolmson and W. E. Parker. Improved fuel. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

2736. V. Poltavtseff and K. Hodjaian. Means for generating heat from liquid and other fuel. February 17.

4279. C. F. Claus. Purification of water-gas or other producer-gas from sulphur compounds. January 20.

4321. J. Baxter and W. Baxter. Apparatus for refining paraffin. January 20.

5212. W. H. Munns.—From E. de Beauharnais. Manufacturing illuminating gas. February 3.

6134. J. Laing. Distillation of mineral oils, &c., and apparatus therefor. February 17.

17,351. G. R. Prowse. Apparatus for forming oxycalcium lights. January 20.

18,498. H. H. Lake.—From C. H. Wilder. Manufacture of gas from hydrocarbon oils, and apparatus therefor. February 10.

19,641. T. G. Springer. Manufacture of gas, and apparatus therefor. February 10.

21,881. W. Fairweather.—From The Acme Liquid Fuel Co. Process and apparatus for the manufacture of gas. January 20.

22,347. W. L. Rowland. Recovering cyanides from coal-gas. February 17.

1892.

535. G. M. S. Wilson. Improvements in the manufacture of gas. January 11.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, &c.

APPLICATIONS.

2129. H. Saxl. Process and apparatus for the production of benzol and its homologues, phenol, naphthalene, and anthracene, from resins or resin oils alone, or mixed with petroleum, petroleum residues, illuminating gas, and other hydrocarbons. February 3.

2367. L. Sepulchre. See Class II.

COMPLETE SPECIFICATION ACCEPTED.

1891.

6134. J. Laing. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

802. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of dyes of the rosauiline series and of leuco-compounds thereof. January 14.

22,641A. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of azo-colours on fibre. Filed January 22. Date applied for December 28, 1891.

960. A. Bang.—From G. A. Dahl, Germany. The production of fast yellow mordant dyeing azo-dyestuffs. Complete Specification. January 18.

1231. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. January 21.

1390. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. January 23.

1473. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of dyes from substituted derivatives of diamido-diphenylmethane. January 25.

1657. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of colouring matters derived from anthraquinone. January 27.

2324. Brooke, Simpson, and Spiller, Limited, and R. J. Friswell. A new substance suitable for dyeing and other purposes and the process for its production. February 6.

2408. C. D. Abel.—From The Actier: Gesellschaft für Anilin Fabrikation, Germany. New manufacture of bases and of colouring matters therefrom. February 8.

2617. O. Imray.—From Die Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of ethoxy-phenylmethylpyrazolone and of para-ethoxy 1 phenyl-2'3 dimethyl-5 pyrazolone. February 10.

2718. S. Pitt.—From L. Cassella and Co., Germany. Improvements in the production of black dyes suitable for dyeing wool. February 11.

2789. S. Pitt.—From L. Cassella and Co., Germany. Improvements in the production of azo dyes. February 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

3622. R. Vidal. Production and separation of methylamines, ethylamines, phenylamines, and naphthylamines. February 10.

5103. R. Holliday and Sons, Lim., T. Holliday, and P. R. E. Seidler. Manufacture of a sulpho-acid of alpha-naphthol and of colouring matters therefrom. February 10.

3269. W. Majert. Manufacture of aromatic glycoecoll derivatives. January 27.

5437. W. Sherwood. A new or improved composition of ink for reproduction of copies by the manifold process. February 10.

5904. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of black colouring matters. February 10.

21,249. E. von Portheim. Manufacture of new colouring matters from naphthyl glycolines. January 27.

22,623. J. Imray.—From La Soc. L. Durand, Haegenin, et Cie. A new manufacture of colouring matters. February 3.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

840. J. Porritt, A. Porritt, M. Porritt, and S. J. Chadwick. A new yarn and process of manufacturing the same from waste fibres. January 15.

1077. W. P. Thompson.—From J. B. Jaensonlin and G. Oser, France. Improvements in treating or decortiating ramie and other similar fibres and in machines therefor. January 19.

1728. C. F. Dietrich and T. J. Palmer. Improvements in the manufacture or production of floor coverings or like materials with coloured designs or patterns and apparatus to be employed in the said manufacture. January 28.

1729. C. F. Dietrich and T. J. Palmer. Improvements in the manufacture and production of materials suitable for use as floor coverings, or for other analogous purposes. January 28.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

6294. J. Daw, jun. An improvement in dyeing mats, carpets, or other fabrics. January 20.

13,072. J. P. A. Blaye. Treatment of ramie fibre, flax, or hemp in the green or dried state. January 20.

17,642. F. J. H. Sampson. Process and appliance for obtaining fibre from rhea. February 17.

1892.

209. D. E. Coe. Manufacture of yarn from waste. February 10.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

22,641A. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of azo colours on fibre. Filed January 22nd. Date applied for December 28, 1891.

1506. J. Dawson. Improvements in the method of and apparatus for utilising the heat of spent liquors or liquids for dyeing, manufacturing, and other like purposes. January 26.

2096. W. Searle and W. H. Elliot. Improved apparatus for dyeing or chemically treating and drying paper, felt, or other fabrics. Complete Specification. February 3.

2730. G. H. Craven. Improvements in dyeing machines. February 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

22,263. L. Kern. Method and apparatus for preventing the escape of noxious gases in the processes of bleaching and otherwise treating textile materials. January 27.

22,437. C. Kellner. Process and apparatus for bleaching paper pulp, and other similar vegetable substances. February 3.

22,438. C. Kellner. Process and apparatus for increasing the bleaching properties of chlorine gas. January 27.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

610. F. Valentiner. Process and apparatus for the manufacture of concentrated nitric acid. January 12.

714. J. R. Thame. An improved process for the manufacture of the cyanides of sodium and potassium. January 13.

1032. P. Rogation de Lambilly. A new or improved method or process for the production of alkaline cyanides. Complete Specification. January 19.

1439. I. S. McDougall and J. T. McDougall. Improvements in the treatment of certain corrosive or poisonous liquids to render them capable of being transported, stored, or used with less danger than hitherto. January 25.

1548. P. Römer. An improved manufacture of potassium carbonate from potassium sulphate. January 26.

1642. O. Imray.—From M. M. Rotten, Germany. Improved manufacture of sodium and potassium bichromates. January 27.

1652. C. F. Claus. Improvements relating to the manufacture of alkaline sulphides and carbonates, and to the production or recovery of sulphide of hydrogen and other by-products. January 27.

1659. C. F. Claus. Improvements relating to the manufacture of alkaline sulphates, sulphides, and carbonates, and to the production or recovery of the hydrate of alumina, sulphide of hydrogen or sulphur, and hydrochloric acid or chlorine. January 27.

1692. G. E. Davis and A. R. Davis. Improvements in the preparation of chlorine. January 28.

1855. J. J. Tate and A. S. Ramage. Improvements in the utilisation of ferrous chloride liquors, especially those known as "waste pickle," from galvanising and tin-plate works. January 30.

2165. C. H. Cribb. Improvements in the production of carbon dioxide and lime from causticising refuse and from limestone and the carbonates of other alkaline earths, and in apparatus therefor. February 4.

2389. L. Brunner and A. Zanner. An improved process for preparing at the same time neutral sulphate of soda and precipitated phosphate of lime. Complete Specification. February 8.

2415. J. Wetter.—From the Firm of H. and E. Albert, Germany. Process for obtaining alkali phosphates from neutral or acid alkali sulphates. February 8.

2604. J. Morris. New or improved process for the production of crystals and crystalline masses. February 10.

2697. A. MacFarlane. A substitute for the acid tartrate of potassium. February 11.

2878. C. W. Kriens. Improvements in the manufacture of nitrates. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

1453. E. O. Lambart.—From S. Piek. Manufacture or production of salt from brine. January 27.

2252. P. G. W. Typke. Manufacture or production of certain phosphorus compounds. February 10.

4661. W. Mills. Manufacture of alkali and apparatus therefor. February 17.

4730. C. Marriott. Apparatus used in the manufacture of sulphate of ammonia. January 27.

5819. D. Rowat and J. Fullerton. Treatment of pickles and apparatus therefor. February 17.

5844. A. G. Haddock and L. Leith. Manufacture of alkali. February 17.

6388. P. J. B. Vincent. Manufacture of salt in blocks and cakes. February 3.

6500. J. Kolb. Production of chlorine. January 20.
 10,629. E. Edwards.—From O. Guttman and L. Rohrmann. Apparatus for condensing nitric acid. January 20.
 20,060. C. Kellner. Process and apparatus for the manufacture of hydrogen and chlorine from hydrochloric acid. January 20.
 22,320. La Soc. A. R. Pechiney et Cie. Manufacture of chlorine from hydrochloric acid gas. February 3.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

697. B. J. Brearley and F. T. Brearley. Improvements in machinery or apparatus for rolling glass. January 13.
 1943. G. Sowerby. Improvements in apparatus for and the method of melting glass. February 1.
 1974. W. Leuder. A new and improved process of marking glass by acids. Complete Specification. February 2.
 2375. Sir A. Hickman. Improvements in the composition and manufacture of refractory and basic bricks and tuyeres. February 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

4391. T. C. J. Thomas. Manufacture of glass. January 20.
 4610. F. Plant. Improvements in ovens, kilns, or furnaces for firing pottery or earthenware, and for other purposes. January 20.
 5068. F. Query. Kilns for use in the manufacture of pottery, porcelain, and earthenware, and other similar goods. January 27.
 5324. W. Walker. Production of glass-making materials. February 3.
 6257. W. C. Gibson. Kilns for bisuiting and burning glazed and enamelled clay goods. February 17.
 20,438. W. P. Thompson.—From R. S. Pease. Method and apparatus for manufacturing glass plates, sheets, and films. January 20.
 20,440. W. P. Thompson.—From R. S. Pease. Method and apparatus for producing cylinders, pipes, and other tubular bodies of glass. January 20.
 21,826. M. Epstein. Filtering tubes with ball-filtering material for purifying molten glass. January 20.

1892.

489. H. Warrington. Kilns for bricks, earthenware, porcelain, &c. February 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

736. T. J. Davey. Chamber oven for drying clay from slurry or any other materials of a similar nature in brick or cement works. January 14.
 795. E. Websky. Improvements in treating gypsum casts. Complete Specification. January 14.
 1195. A. Willard. Improvements in the manufacture of artificial stone. January 21.

1827. W. Brown. Improvements in the method of jointing concrete paving. Complete Specification. January 30.

1861. A. J. Campion. Improvements in the manufacture of hydraulic cement and concrete. January 30.

2131. F. W. S. Stokes. Improvements in apparatus connected with the continuous treatment of lime, cement, and the like materials, and in the lining of kilns and furnaces for burning materials of a basic character. February 4.

2165. C. H. Cribb. See Class VII.

2259. T. White. Improvements in the burning of bricks and cements, and in the manufacture of domestic and other fuel. February 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

2598. J. Ballantine. Improved medium or composition for decorative purposes. February 17.
 4750. La Soc. Anon. des Ardoisieres de Deville and V. Van der Heyden. Manufacture of material suitable for paving, building, &c. from waste pieces of slate. January 27.
 6011. J. Craven. Kilns for burning bricks, &c. February 17.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

540. A. Räder. A solder for aluminium. January 11.
 581. G. Pickhardt. Improvements in connexion with the use of aluminium and aluminium alloys. Complete Specification. January 12.
 890. W. Hutchinson. Improvements in the manufacture of iron and steel. January 16.
 1074. J. B. Alzugaray. Improvements in the treatment of certain ores, alloys, mattes, slags, and other compounds. January 19.
 1205. C. Emo. Improvements in the manufacture or production of aluminium. January 21.
 1211. J. F. Krebs. Method of preparing plates of aluminium or nickel or aluminated or nickeled plates for lithographic use. January 21.
 1273. W. Hutchinson. Improvements in the manufacture of iron and steel. January 22.
 1341. T. Twynam and J. Colley. Improvements in the manufacture of steel and iron. January 23.
 1368. A. J. Thorman. Treatment of iron sand, iron ores, and residuums containing iron. January 23.
 1443. R. B. Thomas. An improvement or improvements in coating sheets or plates of iron and steel with lead. January 25.
 1467. C. Moldenhauer. Improvements in the process of recovering precious metals from their ores. January 25.
 1471. A. Thomas. An improved process for the recovery of metals from their solutions. January 25.
 1530. G. W. Clark. Improvements in the manufacture of steel. January 26.
 1565. H. H. Lake.—From J. Gould, jun., United States. Improvements in and relating to the coating of metal plates, and to apparatus therefor. Complete Specification. January 26.
 1654. C. Hoepfner. Improvements relating to the extraction of silver. January 27.
 1776. W. Hutchinson. Improvements in the manufacture of iron and steel. January 29.
 1795. W. Gilchrist. Improvements in the treatment of iron. January 29.

1901. T. C. Fawcett, sen., T. C. Fawcett, jun., and G. Dyson. Improvements in cupolas or furnaces for melting iron. February 1.

1907. W. Muir. Improvements in the extraction of tin and other products from the refuse slags and debris of tin smelting furnaces. February 1.

1939. C. T. J. Vautin. Improvements in the method of and apparatus for hardening, tempering, or annealing metallic wire or tape. February 1.

1984. D. Dyrenforth. Improvements in the manufacture or treatment of iron. Complete Specification. February 2.

2193. N. Lébédoff. Improvements in the extraction and treatment of metals. February 4.

2214. T. D. Bottomo. Improvements in the casting and tempering of pure copper. February 5.

2241. N. Lébédoff. Improvements in the manufacture of aluminium alloys. February 5.

2261. B. Rösing and the Firm of M. Foerster. Improvements relating to the extraction of lead and to apparatus therefor. February 5.

2299. J. M. While. Improvements in the manufacture of iron. February 6.

2498. S. H. Brown and M. McBarron. Improvements in and relating to the annealing of metals. Complete Specification. February 9.

2583. J. Woodcock, J. Smith, and W. M. Mackey. Improvements in preparing ores, oxides, and compounds of iron for smelting. February 10.

2590. W. K. Greenway. Improvements in galvanising iron and steel. February 10.

2594. W. K. Greenway. Improvements in galvanising or coating iron with other metal or metals. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

1309. J. H. Pollok. Gold extracting reagents. January 20.

1374. A. M. Clark.—From La Société Anonyme de Produits Chimiques Etablissements. Treating ores and residues containing zinc by means of bisulphate of soda for the production of commercial products. January 27.

2508. A. de L. Long and J. Noble. Gas regenerative vertical ingot heating furnace. January 20.

4050. M. Mammesmann. Method of and apparatus for forming, rolling, and finishing metals. February 10.

4384. J. von Ehrenwerth. Processes and appliances for the manufacture of iron and steel. January 20.

4549. W. E. May. The casting and working of metals, and to apparatus for use in connexion therewith, and for other purposes. January 20.

4644. J. O. Arnold. Manufacture of steel ingots, steel castings, and ingot iron. February 10.

6246. W. S. Lockhart and E. W. Streeter. Process and apparatus for the separation of metals, precious stones, or other mineral from gangue, &c. mixed therewith. February 17.

10,985. F. H. Mason. Extraction of tin from tin slags and refuse by lead or its salts, carbonaceous matter, fluor-spar, and other suitable fluxes. January 20.

14,737. W. D. Bohm. Apparatus for leaching ores and separating gold and silver therefrom. January 27.

14,795. E. Martin. Manufacture of compound or metal coated wires. February 10.

19,330. J. Johnson.—From J. Gayley. Blast-furnace linings. January 3.

22,041. C. James. Treating plumbiferous copper mattes and ores. January 20.

22,177. T. J. Tresidder. Manufacture of armour plates. February 3.

22,694. E. Dor. Regenerative gas furnace for the reduction of zinc ores. February 10.

1892.

540. A. Räder. A solder for aluminium. January 11.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

645. P. Gendron. Improvements relating to electric welding. Complete Specification. January 12.

982. T. Parker, A. E. Robinson, and C. H. Parker. Improvements in or connected with the manufacture or production of chloride of zinc and alkaline sulphates, and of zinc and chlorine by electrolysis of solutions thereof. January 18.

1038. H. Koller. A new or improved manufacture of an exciting material for galvanic batteries. January 19.

1061. E. Hermite. Improvements in bleaching and disinfecting starch and fecula by electrolysis. January 19.

1141. C. Vogt. Improvements in dry electrical elements. January 20.

1145. H. A. Walker. Improvements in the manufacture of siliceous insulating material for electrical and other purposes. January 20.

1391. The London Metallurgical Co. and S. O. Cowper-Coles. Improvements relating to the coating of articles with a new metallic alloy by electro deposition. Complete Specification. January 23.

1426. C. G. Moor. Improvements in electrical batteries. January 25.

1484. J. B. Eutz and W. A. Phillips. Improvements in and relating to secondary batteries. Complete Specification. January 26.

1786. R. Pinna. Improvements in or relating to tanning by electricity. January 29.

1927. W. J. S. Barber-Starkey. An improvement in secondary voltaic batteries. February 1.

2106. H. Howard. Improvements in heating and welding by electricity. February 3.

2225. G. Nahsen. Improvements in the method of purifying electrolytes containing zinc, relating to or connected with the electro-metallurgical production of zinc. Complete Specification. February 5.

2329. O. Imray.—From T. J. Montgomery, United States. Improvements in process and apparatus for bleaching by electrolysis. Complete Specification. February 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

1049. S. Z. de Ferranti. Manufacture of dynamo-electric machines. January 27.

3417. W. H. Munos.—From G. A. Smith. Galvanic battery. January 20.

4757. T. L. Wilson. Electric reduction of aluminium and other metals, and production of alloys thereof. January 20.

4781. W. J. Eogledew. Solution for galvanic batteries. January 20.

4860. H. Howard. Apparatus for heating and welding by electricity. February 10.

4877. H. H. Lake.—E. A. G. Street and L. A. W. Desruelles. Production of porous materials and manufacture of same into electrodes for batteries. January 20.

5918. H. I. Harris and W. H. Power. Electric batteries. February 10.

5999. J. Greenwood. Production of chlorine and sodium amalgam. February 17.

6029. W. H. Walenn and I. A. Timmis. Electro-deposition of copper, brass, and bronze, applicable to other purposes. February 17.

6030. W. H. Walenn and I. A. Timmis. Electro-deposition of copper, brass, or bronze. February 17.

21,870. H. H. Lake.—From E. A. Clarke. Voltaic cells or batteries. January 20.

22,482. H. H. Lake.—From E. Weston. Voltaic cells. February 10.

1892.

645. R. Gendron. Improvements relating to electric weldings. January 12.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

952. W. S. Chenall and W. F. S. Chenall. *See* Class II.
2257. J. J. Speakman. Improved washing compounds. February 5.

2320. F. Hughes.—From A. Motte & Co., France. A new or improved mechanical process for winning the fatty matters contained in the water used for washing wool, and for commercial and domestic purposes. Complete Specification. February 6.

2482. A. Lobmann. Improvements in lubricating materials. February 9.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

747. H. Wyatt, jun. A method for making a solution of vegetable or other resins and resinoids for internal use. January 14.

790. W. Smith. Improvements in the manufacture of white lead by the acetate of ammonia process, more especially in respect of the regeneration and recovery of acetate of ammonia from the weak liquors and washings furnished in the process. January 14.

910. A. W. Harrison. An improved blacking. January 16.

1229. H. Traun. Improvements in and relating to the manufacture of hardened caoutchouc. January 21.

1882. D. Swan. Improvements in obtaining pigments. February 1.

2183. W. G. Taylor.—From the Gutta Percha Syndicate, Limited, Straits Settlements. Method of and process for obtaining gutta-percha from trees of the Sapota family. February 4.

2201. R. I. Clark. An improved manufacture of varnish. February 4.

2253. C. H. Bigland. Improvements in paints or protective coverings for ships' bottoms and other structures. Complete Specification. February 5.

2562. W. L. L. Grant and H. P. T. Dennys. An antifouling and preservative paint for protecting the bottoms of iron or wooden vessels, or other submerged surfaces. February 10.

2563. A. F. St. George. An improved substitute for and compound resembling india-rubber, and manufacturing the same. February 10.

2605. J. Dawson. An improved composition for removing varnish, paint or polish. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

2382. G. W. Seollay. Manufacture of paints or paint stock. February 10.

5501. W. Smith and W. Elmore. Production of white lead or basic carbonate of lead from galena or sulphide of lead ore, or from residual products containing sulphate of lead. February 10.

5681. C. A. Burghardt. Pigments having a lead basis. February 10.

6306. W. P. Thompson.—From A. Flugge. Production of a solution of myrrhic resin. February 10.

20,253. R. Ripley. The form or get-up of bag-blue. February 3.

20,274. R. Lender. Rust and acid-proof paint. February 10.

20,407. R. Pape. Manufacture of a hard insulating material. February 3.

21,279. W. J. Wigg. Manufacture of Venetian red. February 10.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

544. J. Menke. Improvements in artificial leather. January 11.

698. A. J. Boulton.—From E. Rauppach and L. Bergel, Austria. Improvements in or relating to the manufacture and use of glue. January 13.

838. S. Thorn. Improved substitutes for tannin of an article in substitution of what is commonly known as tanned leather. January 15.

951. L. Berram. Improvements in process and apparatus for extracting glue or gelatin and grease out of hide and skin waste, and of bones at comparatively low temperature. Complete Specification. January 18.

2429. H. E. Howe. An improved method of rendering leather used for the outer soles of boots and shoes flexible or pliable. Complete Specification. February 8.

COMPLETE SPECIFICATION ACCEPTED.

1891.

12,331. J. Shepherd.—From A. Krizek and R. Esche. Mineral size. February 3.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

1583. W. L. Wise.—From C. d'Abbadie de Barran, Island of Mauritius. Improvements in apparatus for use in the manufacture of sugar. January 26.

1858. W. L. Wise.—From C. d'Abbadie de Barran, Island of Mauritius. Improvements in apparatus suitable for cooling cane-juice and other substances. January 30.

2693. J. G. Healey. A new or improved liquid cement. February 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

5236. A. Schneller and W. J. Wisse. Refining or extracting sugar from raw sugar solution, juice, or molasses. February 3.

21,059. C. Kleyer and C. Kappesser. See Class XIX.

22,679. C. M. Higgins. Mucilages, sizes, and adhesive compounds. February 3.

22,682. C. M. Higgins. Mucilages, sizes, and adhesive compounds. February 3.

22,685. C. M. Higgins. Mucilages, sizes, and adhesive compounds. February 3.

1892.

420. E. Langen. Refining sugar. February 17.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

911. R. H. Leaker. An improved method of and apparatus for kilning malt. January 16.

1043. G. Bamberg. Improvements in the manufacture of condensed beverages. January 19.

1044. J. F. Henderson. Improvements in or applicable to the manufacture of unfermented grape wine. Complete Specification. January 19.

1445. J. S. Olver. A method of regulating the moisture and respiration of malt growing under the pneumatic system. January 25.

1738. W. P. Thompson.—From J. W. Meeus, Belgium. Improvements in apparatus for registering the flow of liquids in connexion with distilling, rectifying, or other apparatus. January 28.

1863. J. G. Hall. A new and improved refrigerator or apparatus for cooling wort and other liquids, and for other similar purposes, principally used in breweries and distilleries, applicable for condensing steam, spirit, or other vapours. January 30.

2210. J. Chalmers and J. W. Phillips. Cooling wort, to be called a refrigerator for cooling wort. February 5.

2678. H. de Soberon. Improved liquor, resembling brandy, and process for manufacturing the same. February 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891

5853. W. Heasman. Means for the hot aëration of wort. February 10.

21,059. C. Kleyer and C. Kappesser. See Class XIX.

21,708. S. Pitt.—From A. Savalle, Sons, and Co. Apparatus for distilling and rectifying. January 20.

22,124. C. H. Jolliffe. Apparatus for roasting, aërating, and attenuating brewers' worts during the process of fermentation. January 27.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

1055. J. H. Bovenkerk, jun., and A. C. Knyt. Improvements relating to the preservation of milk. January 19.

1150. K. G. Krikorian. A new or improved method of treating and roasting malt, and blending the same for infusion together with coffee. January 21.

1717. S. Saker and W. C. Glover. The manufacture of a compound for use in preparing infusions of tea. January 28.

2421. J. F. Boesen. A new or improved manufacture of meat extract. Complete Specification. February 8.

ERRATUM.—In December Journal, p. 1051, for No. 21,708, S. Pitt, read No. 21,706, O. Imray.

B.—Sanitary Chemistry.

1567. A. Leveux. Improvements relating to the treatment of sewage and other refuse, and to apparatus therefor. January 26.

1609. W. M. Greaves. Improvements in the treatment of sewage and other refuse. January 27.

2560. H. Lockwood. Improvements in the method of purifying sewage by means of lime in conjunction with a salt of iron. February 10.

C.—Disinfectants.

755. A. Gladstone. An improved antiseptic dressing for yarns and cloth. January 14.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

2051. J. Y. Johnson.—From La Société Générale Herscher and Co. Means or apparatus for sterilising water. February 10.

2444. L. Smith. Means for storing and preserving food for domestic uses. February 10.

20,419. J. E. Alén. Method of preventing the curdling of albuminous solutions. January 27.

1892.

279. A. D. McKay. New chemical food. February 17.

B.—Sanitary Chemistry.

1891.

10,092. F. Livet. Apparatus for creaming house-dust and like refuse on new sanitary principles. February 3.

C.—Disinfectants.

1891.

4352. A. Lutschaunig. A new or improved manufacture, being a disinfectant, antiseptic, deodoriser, vermin and insect destroyer, and also applicable for use as an ingredient in fire-lighters. January 20.

5263. J. Y. Johnson.—From F. von Heyden. Improvements in the production of salicylic acid derivatives containing chlorine and sulphur. January 20.

20,495. A. Robertson. Sheep dip. February 17.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

669. F. Hawke and W. Mottershall. A new and improved carbon or carbonic paper for manifolding, duplicating, and like purposes. January 13.

709. H. H. Lake.—From H. M. Lenfant, veuve Vessier, France. Improvements in washing apparatus for use in the manufacture of paper. January 13.

2185. W. Jones. Improvements in or relating to the manufacture of transfer paper. February 4.

2629. V. B. Drewsen. An improved method of purifying the liquid which has been used in the manufacture of cellulose and the production of useful products therefrom. Complete Specification. February 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

6589. C. Lenz. Manufacture of paper and cardboard. February 17.

21,059. C. Kleyer and C. Kappesser. Treatment of peat for the production of cellulose, sugar, and alcohol. February 10.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

NOTICES.

The Annual General Meeting will be held in London on the 20th, 21st, and 22nd July next. Full particulars will appear in a subsequent issue.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary will be glad to hear from Members possessing odd copies of the Journal for January 1882; January, March, and May 1883; complete Volumes 1886; and February and July 1889—all of which are now out of print. He is prepared to offer 5s. apiece for January 1882, January, March, and May 1883. Members who possess spare copies of these numbers are requested to communicate at once with Mr. Cresswell.

LIST OF MEMBERS ELECTED, 23rd MARCH 1892.

Adams, Arthur, Broomfield Place, Smethwick, Birmingham, science lecturer.
 Bachke, A. A., Røros Vaerk, Røros, Norway, chemist and smelter.
 Baker, Julian L., Stamford, Hendham Road, Upper Tooting, S.W., sugar chemist.
 Bowes, Harry, 9, Union Terrace, Cheetham Hill, Manchester, analytical chemist.
 Clayton, Jas. S., Ewbank, Accrington, M.B.
 Crippin, Wm., The Hollies, Eccles, Manchester, dyer.
 Crossman, Tom, Albion Brewery, Coldhurst Street, Oldham, brewer's chemist.
 Eddy, Harrison P., Sewage Purification Works, Worcester, Mass., U.S.A., superintendent.
 Elliot, John, Free Library, Wolverhampton, librarian.
 Fanta, F., 85, Gresham Street, E.C., consulting engineer.
 Flanagan, Chas. A., Globe Hotel, Regent Road, Manchester, manufacturing chemist.
 Houston, Jno., 111, Charlotte Street, Manchester, dyersaler.
 Jenkins, Thos. Herb., 5, Bellott Street, Cheetham, Manchester, analytical chemist.
 Josland, W. H., 9, Campbell Grove, Oxford Road, Manchester, analytical chemist.
 Judd, Geo. M., 207, Burdett Road, Bow, E., manager.
 Kibble, W. Oakes, Norton Villa, Buckhurst Hill, Essex, chemical engineer.
 Mayfield, Harry B., Fairview House, Heanor, near Nottingham, dyer.
 Mayfield, Thos., Fairview House, Heanor, near Nottingham, hosier.
 Ouslikoff, P. K., Elabouga, Government of Viatka, Russia, chemical manufacturer.
 Peploe, D. H. T., 39, Sloane Gardens, London, S.W.
 Phillips, H. J., Great Eastern Railway Works, Stratford, E., analytical chemist.
 Richardson, G. E., Howley Park, Batley, Yorks, manufacturing chemist.
 Schlichter, Hermann C., Kammgarn Spinnerei, Leipzig, analytical chemist.
 White-side, Jno. L., 51, Cannon Street, Bolton, chemical lecturer.
 Wild, Wm. Ernest, 2, Stanton Villas, Eccles New Road, Salford, analytical chemist.
 Wilkinson, Dr. S., 51, Arcade Chambers, St. Mary's Gate, Manchester, analytical chemist.
 Wingfield, T. R., Nelson Square, Bolton, brewer.
 Winslow, Harry, c/o Kames Gunpowder Company, Kyles of Bute, chemist.

CHANGES OF ADDRESS.

Aron, S. B. Asher, 1/o Maida Vale; 23, Westbourne Park Crescent, W.
 Auerbach, Dr. C. G., 1/o Friesenheimer Strasse; 7, Breite Strasse, Ludwigshafen a/Rhein.
 Bourcart, Dr. R., 1/o Geneva; 31, Rue Duquesne, Lyons, France.

Burton, Wm., 1/o Stoke; 45, Liverpool Road, Newcastle, Staffordshire.
 Colman, Dr. H. G., 1/o Monument Road; 28, Duchess Road, Edgbaston.
 Cornish, V., 1/o George Hotel; 1, St. James Terrace, Winchester.
 Fawcett, J. H., 1/o Bank of Australasia; Broken Hill Assay Office, 72, Mark Lane, E.C.
 Francis, Wm., 1/o Belfast; c/o Pollok Patents Gold Extracting Co., Taltal, Chili.
 Glaser, C., Journals to c/o Bradley Fertilizer and Chemical Co., Baltimore, Md., U.S.A.
 Hastings, Hugh, 1/o Birmingham Road; 10, Yew Tree Road, Kidderminster.
 Helm, H. J., 1/o Catford; Simonstone, Hammelton Road, Bromley, Kent.
 Hollman, F. R., Journals to Sugar Refinery, Rawcliffe Bridge, R.S.O., Yorkshire.
 Hopkin, W. K., 1/o Mowbray Road; Fernbrae, Brondesbury Park, N.W.
 Hunt, Alf. E., 1/o 5th Avenue; 272, Shady Avenue, East End, Pittsburgh, Pa., U.S.A.
 Hutchinson, A. H., 1/o Clapton; c/o Gold Ores Reduction Co., 34, Moorgate Street, E.C.
 Johnson, T. A., 1/o Warrington Park; Field House, Warrington, Northwich.
 Koechlin, H., 1/o Loerrach; 16, Rue Masséna, Lyons, France.
 Lake, G., jun., 1/o Turnlee Road; 83, Primrose Lane, Glossop, Derbyshire.
 Loewenthal, Dr. R., 1/o Manchester; Sommerfeld, N.L., Germany.
 Ludlow, L., Journals to c/o Cape Copper Co., Lim., Ookiep, Namaqualand, South Africa.
 Mackenzie, T. E., 1/o Glasgow; Dalzell Iron and Steel Works, Motherwell, N.B.
 Newton, H. C., 1/o Hampstead; 47, Calcott Road, Brondesbury, N.W.
 O'Beirne, W. G., 1/o Partick; British Chemical Works, Clydebank, Glasgow.
 Peace, F. K., Journals to G.P.O., Sydney, New South Wales.
 Roberts, F. A., 1/o Warrington; Cornbrook Chemical Works, Manchester.
 Roberts, J. H. M., 1/o Barton; 16, Kinglake Street, Liverpool.
 Roseow, Jas., Journals to Birch Vale, *via* Stockport.
 Sanford, P. Gerald, Journals to 20, Cullum Street, Fenchurch Street, E.C.
 Schlichter, Dr. H., 1/o Alma Square; 3, Wells Villas, Whittington Road, Bowes Park, N.
 Shimidzu, T., 1/o Tokyo; c/o J. Takamine, 907, Chamber of Commerce, Chicago, Ill., U.S.A.
 Tasker, G., 1/o Langside; 1048, Cathcart Road, Mount Florida, Glasgow.
 Watson, Eric E., retain Journals until further notice.
 Williams, Rowland, 1/o Manchester; Lancaster.
 Wilson, Dr. W. H., 1/o Kensington; 18, Kimbolton Road, Bedford (until October 1).

CHANGES OF ADDRESS REQUIRED.

Orchard, John, 1/o 100, High Street, Kensington, W.
 Palmer, Thos., 1/o Temple Chambers, Temple Avenue, E.C.

Deaths.

Dr. T. Redwood, Boverton, near Cowbridge, Glamorgan-shire.
 Dr. C. Meymott Tidy, 3, Mandeville Place, Manchester Square, W.
 Joseph Townsend, 19, Crawford Street, Port Dundas, Glasgow.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyer.

Vice-Chairman: W. Crowder.

Committee:

C. F. Cross.
J. Dewar.
A. G. Green.
S. Hall.
C. W. Heaton.
D. Howard.
W. Kellner.

W. Ramsay.
B. Redwood.
W. S. Squire.
G. N. Stoker.
F. Nanier Sutton.
Wm. Thorpe.
T. E. Thorpe.

Hon. Local Secretary: John Heron,
St. John's Villas, Werpel Road, Wimbledon.

SESSION 1891-92.

1892:—

April 4th:—

Dr. C. R. Alder Wright, F.R.S. "On Specific Gravities for Practical Purposes."

Mr. H. B. Fulton. "Note on Specific Gravity Apparatus."

Mr. Albert Baur, Ph.D. "On Artificial Musk."

Mr. F. H. Leeds, F.I.C., F.C.S. "Note on Rosin Oil."

Election of Officers and Five Members to the Local Committee.

May 2nd:—

Professor Wm. Ramsay, F.R.S., and Mr. J. C. Chorley. "The Distillation of Wood."

Dr. S. Rideal. "Notes on the Composition of some Indian Gums of known Origin."

June 6th:—

Mr. J. A. Nettleton. "Vinegar."

Dr. S. Rideal. "The Petroleum Jellies of Commerce."

Meeting held Monday, 7th March, 1892.

MR. THOS. TYER, IN THE CHAIR.

THE DANGERS IN THE MANUFACTURE OF EXPLOSIVES.

BY OSCAR GUTTMANN, ASSOC.M. INST.C.E.

With a few exceptions the dangers in connexion with explosives may be summed up in the terrible word, "Explosion." Those who have witnessed one are never likely to forget the impression. A sharp report, huge red flames shooting towards the sky, followed by indistinguishable dark masses, then a dull shower of falling pieces, followed by a dead silence. Where a second ago a neat-looking building stood, and busy hands were working, there is now a deep hole in the ground, and all around at great distances lie scattered the fragments of house, machinery, and workers. It is difficult even to identify these last. Their clothes, if not of wool, are burnt away, their features are no longer recognisable, and sometimes a foot on a limb, or a mark on a body is the only clue. The cause of the explosion can rarely be traced with certainty. Whoever has read the reports of Her Majesty's Inspectors of Explosives will have nearly invariably found more than one possible cause given, but they will at the same time have been astonished to find a power of generalisation displayed which has never yet failed to teach some sound moral for the benefit of those concerned. Unfortunately such reports are published only in Great Britain, and the few short notices which reach other countries are quite insufficient to give the manufacturers adequate information to enable them to provide effectively for the protection of their workpeople and their property. A feeling that it is the duty of each one to relate his experiences has led the author to give an outline of the sources of danger involved in the manufacture and use of explosives.

It is generally agreed that an explosion must first be defined as the *sudden* decomposition of a mechanical or chemical mixture into its components, whereby in a short space of time a great pressure is developed. Such an explosion may be started by different means and they are by no means the same in every case. Sometimes ignition will start the decomposition, sometimes a shock, friction, an electric spark, vibration, sudden heating, &c.; but as a rule it is necessary, as Sir Frederick Abel pointed out first, that a certain amount of vibration and vibration of a distinct nature be generated as a result of either of the above causes, in order to produce explosion.

The explosion is quicker, the larger the number of vibrations in unit time. The stronger the effect, the higher the heat produced and the larger the quantity of gases developed, as their expansion increases in proportion to their temperature. An explosion has the maximum effect, when the vibrations, the heat and the quantity of gas reach their maximum at the same time.

Here may be mentioned some of the more conspicuous cases of explosions.

Chloride of nitrogen explodes when thrown into boiling water. If a minute piece of paper, smeared with iodide of nitrogen, the temperature of explosion of which is 212°F. , be allowed to fall from a height of about 3 feet, it will explode on touching the ground. If such a piece of paper is put on a bass-violin and the E chord is struck, it is not influenced, but, if the G chord be struck, which gives more than 60 vibrations in the second, it explodes. If a gunpowder mixture be ignited in a tamped borehole it burns away by layers until the pressure of gas and the heat cause explosion. If dynamite be ignited in this way it will simply burn without detonation. If laid on an anvil and struck sharply at an angle ("glancing blow") all explosives in practical use will detonate. Dynamite explodes between steel and steel when 5·63 footpounds of work are done upon it (0·78 kilogramme-metres), gunpowder at 56 footpounds (7·57 kilogramme-metres); but whereas the explosion travels through the whole of the gunpowder, dynamite as a rule only detonates in the part struck by the blow. If a dynamite cartridge be exploded on the top of a gun-cotton charge the latter will only burn away, but if the places are reversed the gun-cotton is sure to detonate the dynamite. Each explosive has a certain temperature, beyond which it cannot be heated suddenly without detonation. This temperature is for example 212°F. for iodide of nitrogen, from 356° to 363° for nitro-compounds, and 518° to 608° for gunpowder.

It is therefore obvious that an explosion is not solely due to the explosive being heated to a certain temperature. In fact, the shock or friction, that will cause a great many explosives to detonate, may be quite insufficient to raise the temperature to any appreciable extent, even if the shock be concentrated on a single point, as in the case of a "glancing blow."

On the other hand anything which is likely to produce vibrations of a sufficient amplitude and frequency in the explosive should be carefully guarded against. Thus for instance it is well known, that a tuning fork will give a greater number of vibrations, if struck against an object of steel, than against brass, stone, or wood; and the same applies to any shock against an explosive lying between different bodies. Steel against steel is the most dangerous, wood against wood the most harmless. Yet it has been proved by Dr. Dupré that a glancing blow with a broomstick against a wooden floor will cause the explosion of most explosives. Of course it depends greatly in what condition the explosive itself is. A blow given to a full cartridge of blasting gelatin may be quite harmless; but if sufficient force be used to flatten the cartridge and to expose the last thin layer to a sufficient amount of shock, then an explosion of the whole cartridge may follow. There is also a great difference between the explosive being warm or cold. When warm explosives are as a rule more sensitive, both to decomposition and to shock or friction.

The causes of explosion may be placed under two headings, mechanical and chemical. The mechanical causes are mainly due to shock, friction, or ignition of some sort. The chemical causes vary with the nature of the

explosive. Mechanical mixtures, such as gunpowder, roburite, &c., are under ordinary circumstances exempt from dangerous chemical changes, but chemical compounds have always a certain amount of instability, which can only be avoided by careful manufacture. Of course there are also mechanical mixtures, which are liable to decomposition, and I need only mention the chlorate mixtures, which, especially in the case of fireworks, have led to many accidents.

In the following account each explosive will be dealt with separately, and the dangers attached to it at each stage of its manufacture pointed out. Of course only those explosives which are actually manufactured and in use will be spoken of, it being left to you to draw your own conclusions, by the similarity of cases, when other explosives come under your notice.

Gunpowder.

First by seniority and by the number of factories making it comes *gunpowder* and its imitations.

In this case, as in that of every other explosive a very important condition is, that the materials employed should be of the greatest possible purity, both chemically and mechanically.

In the nitrate (saltpetre, sodium nitrate, &c.) chlorine is the principal impurity. Although in the case of true gunpowder no saltpetre is now used which contains more than one ten thousandth part of chlorine, yet with gunpowder imitations, especially where sodium nitrate is used, this is not always the case. An assistant of mine once made some powder mixture, extracted the nitrate, which contained a large amount of chlorine from it, evaporated the solution in a porcelain dish to dryness and complete fusion. He then allowed it to cool, and after some time, began to remove the cake with a glass rod, when suddenly the whole flashed up. In this case it is evident that some nitrogen chloride had been formed, the liability of which to explosion by the slightest vibration is so well known.

Care has also to be taken that no saltpetre or powder comes into contact with a soldered joint. Weber found in a particular case that nitrate of tin was formed, of which there is an explosive variety; this has caused frequent accidents.

The charcoal presents no other danger than that of spontaneous combustion. It is a good practice to have the charcoal first ground in separate machines. Spontaneous combustion is due to the capacity charcoal has of absorbing and condensing the air, producing thereby heat. This may sometimes take place suddenly, as for instance, when a piece of charcoal is broken, and the interior, which has preserved its absorbing power, is brought into contact with moist air.

The sulphur is now generally ground before mixing it with the other ingredients. Although by quick grinding a large amount of heat may be produced, this is scarcely ever sufficient to fire the sulphur. But sulphur mills very often take fire, and this is chiefly due to the well known electrical qualities of sulphur, which are made evident by the friction and heat in grinding. A friend of the author connected his sulphur mills with the earth by means of copper wires so as to carry away the electric charge as it was produced; since this time he has never had a sulphur mill fire.

If a ventilator is used to carry away the sulphur dust, its exhaust pipe should go into a collecting chamber, as sulphur dust is dangerous.

In this country stamp mills are no longer used for the incorporation of gunpowder, but elsewhere they still exist. They have generally wooden beds and brass stamps, and but for the presence of grit, or some broken metal parts, they are safe enough, provided the powder is frequently "liquored." Still, most of the accidents occur with them, as these two conditions of safety are often accidentally absent, and the great amount of dust, thrown in the air by the violent blows of the stamps, takes fire easily by a spark, or by the friction of a stamp pole.

Mixing drums were formerly largely used, and seem to be coming into use again in this country for certain kinds of powders. As they are made of "sole" leather or wood with brass or wood balls revolving in them, there should be

no other danger in them than comes from overheating due to the quick movement. There is still another source of danger which will be dealt with presently.

The machines chiefly used for the intimate mixture of the gunpowder ingredients are the "incorporating mills" having generally pans and runners of cast iron. Sometimes the beds are made of wooden blocks on edge. Incorporating mills are known to explode from time to time, and formerly the well-worn excuse of a match, or a nail having got into the mill, used to be a readily-accepted explanation of the accident. Such an occurrence of course is possible, but must be very rare indeed. The chief cause is faulty construction of the mills. The runners weigh from four to five tons, and if the cake in the course of milling becomes dry and hard, the runner may lift in passing over a thicker piece, and then fall down on to a thin one. Good incorporating mills are now made in such a way that the runners always remain about $\frac{1}{8}$ inch off the bed, so that iron can never come in contact with iron. Another cause, which applies to mixing drums and nearly all other powder machinery, is electricity accumulated by the friction against the sulphur. Some years ago the author advised the "earthing" of incorporating mills, and he believes that the number of accidents has considerably diminished where his suggestion has been adopted. It is known that many of the explosions in incorporating mills happen when they are suddenly stopped or started after a stoppage, whereby a great amount of vibrations are of necessity set up in a single moment. Many accidents happen also in removing the cake from the bed, or when repairs are being made. It is essential and rightly enforced by Her Majesty's inspectors that the cake should only be taken away when damp, and that no repair should be done without having previously thoroughly washed and cleaned the whole building. The use of brass tools in such a case is only a diminution of the risk, and is not by any means a safeguard against accident, and even wooden implements should only be used after the charge is well moistened. To prevent communication between one mill and another, which very often are driven in pairs from one water-wheel or line of shafting, the drenching apparatus has proved to be very effective. Briefly, this is a water-tank placed on the top of the mill, and held in equilibrium by a "shutter," a flat lever board, which, when raised in the least degree upsets the tank. All the shutters are connected by a shaft, so that when an explosion in one mill takes place, all the other charges are immediately drowned.

When an incorporating mill explodes, the building only is, as a rule, damaged, and that not always much. A friend of the author's has adopted the excellent system of constructing the roof of the building with a very light framing, and securing the whole roof by two loose wooden pins only. If an explosion occurs the roof is simply lifted, giving enough opening to the gases to escape before sufficient pressure to materially damage the building can be set up.

The mill cake is next powdered in a "breaking down machine," which is essentially a roller mill with one pair of grooved and one pair of plain rollers. This machine requires no more attention than other powder machinery, except that it should be so made that the pressure on the rollers cannot exceed a certain limit. This is generally done.

Next comes the pressing, which is now generally done by hydraulic machines, roller presses being very rarely used. Formerly this pressing was done by placing in a square wooden box with hinged sides a layer of powder meal and a brass plate alternately, and then pressing a block of hard wood into the box. This caused the powder to adhere so strongly to the sides of the box that it required a good deal of force to open it, and sometimes occasioned accidents. Nowadays the damp powder meal is, as a rule, laid on an ebonite plate, spread out flat with a shovel, and another ebonite plate placed on the top of it, and so on, layers of powder and ebonite alternating until the required height is reached. This way of pressing is comparatively safe, provided great care is taken to keep the presses clean, and the hydraulic ram is not allowed to fall down too quickly. But there is again the danger of electricity, which in this case

especially must not be under-rated. The charge of a cake press with ebonite plates can practically be considered as an electric pile, and a large amount of friction or electric influence from outside may cause a sufficient electric charge to give off sparks. Several cases have been known, and the following instance occurred at a large continental factory. The workman, having just finished charging, opened the valve for the hydraulic pressure, when he became aware of an approaching thunderstorm. According to his instructions he left the building, and returned after the thunderstorm had passed away, but when he began to discharge the press it exploded. The man died, but stated before his death that in undoing the cakes a spark of 4 inches in length came on his finger.

It is therefore advisable to take great precautions in using ebonite. It is a very convenient material, being very tough, of smooth surface, hard and not subject to much wear and yet sufficiently elastic; it is therefore largely used for plates in cake presses, for the lining of hoppers in granulating and sifting machines, &c. but care must be taken that no electricity can accumulate even under unfavourable circumstances.

The reduction of the powder cake into grains is done by a machine similar to that used for breaking down the mill cake; the grains formed are continuously classified as they fall from the rollers by sieves placed underneath. There is a large amount of dust produced in this operation, and the author has not yet seen a single graining machine where the escape of dust into the room has been perfectly avoided, but he has seen many houses where the air looked worse than a London fog, and where with open doors you could see the cloud of powder dust coming out for more than three yards. As a matter of course, there is shafting in the house, the graining machines themselves contain a number of cog-wheels, bearings, &c., and sometimes the shafting itself is driven by a cog-wheel from another line of shafting. These cause a good deal of noise, which together with the darkness in the room produce a very uncomfortable feeling.

In many factories the graining is still done by the Lefebvre system, which consists of one or more sieves oscillating either longitudinally or in a circle, in which a weighted boxwood disc, hewn like a millstone, is moved to and fro, thereby breaking the cake. This way of graining produces of course still more dust.

In some places a ventilator may be found which draws out the powder dust through an opening in the building, and deposits it on sheets of cloth, but it is never efficient enough to clear the atmosphere of the room. It is the author's belief that a suitable casing round the graining machine, and a hood on the top in connexion with a good exhaust, leading in a depositing chamber, would answer the purpose much better. No cog-wheels should be allowed on the shafting inside the building. They do not always gear perfectly, and wear out in time, which causes dangerous knocks, and it would perhaps be advisable to put the shafting altogether outside the house, unless it runs at a low speed. The bearings of the graining machine should be provided with constant lubricators, such as Stauffer's solid grease cups, which prevent the inconvenience of the oil dripping about, and keep the bearings constantly greased.

During the glazing, rounding, and sieving, the powder is subjected to a constant friction of its particles against each other; and during the glazing especially, where there is still a large amount of moisture, a good deal of heat is developed. The plugs in the glazing barrels must be opened at regular intervals to allow the escape of the steam formed, and care should be taken with all these revolving machines to carry away any electric charge that has accumulated, which is easily done.

The drying of the powder is no longer done in the open air, however convenient this may have been. There was always the risk of grit flying into the powder, and of a concentration of the sun's rays, if exposed to it. Artificial heat is now generally resorted to, and in very few cases only are the fumes of a stove carried in pipes to the drying house. Steam, hot or warm water, are nearly always adopted now. The introduction of steam or hot water pipes into the building itself is objectionable, as a certain amount of dust, which is always produced in charging and emptying

the trays, accumulates on the hot pipes. Warm water pipes increase the time of drying a little, but are not open to this objection. The best way is certainly to have a steam or hot water stove outside the building, and to drive, by means of a fan, a current of air over the stove into the drying chamber. This allows an even temperature to be kept, and removes all danger, provided that the air inlet be so arranged that the current of hot air cannot pass directly over a layer of powder.

Sometimes the press cake is cut into large cubes for the so-called pebble or cube powder. No special allusion need be made to these machines, whatever may be their construction, as the exclusion of hard blows, the attention to knives, bearings, &c., is the same as with all other powder machinery.

The process which requires most attention, and which is not always in expert hands, is that of compressing the powder into prisms, cylinders, pellets, &c. There are two classes of presses in use, lever and hydraulic presses. With a lever press generally the powder is charged into a mould, closed at the bottom by a piston, and another piston is brought down on the top by a lever actuated by an eccentric. Of course there are a great variety of such presses. Some have a "block" with many holes, into the bottom of which comes a disc, then the powder charge, then a piston, and the whole goes under a press. In some presses the mould revolves on a table, and its holes are alternately opposite a plain part and a perforated part of the table, and, at the same time, subject to a piston compressing the charge, and, on another part, to a longer piston forcing the compressed cartridge through the hole in the table, whence it falls out in a receptacle. Sometimes a hopper slides over the mould, fills it, glides away, the charge is compressed, the bottom of the mould glides away, and the charge is forced out. Sometimes the mould is fixed, sometimes it is balanced during the compression, whilst a piston enters the mould from the top and from the bottom.

These latter presses are, perhaps, the best in the way of lever presses, provided the mould be guided vertically, and one of the two pistons has a safety arrangement, to prevent excess of pressure. Lever presses, where more than one cartridge is pressed at the time, are objectionable, as they seldom have a safety arrangement, and to make such an one effective would cost as much as a suitable hydraulic press.

It is well known to everybody who has had to do with the compression of pulverulent substances, that it is most difficult to have a number of moulds filled with exactly the same quantity in each. Even little hoppers, which open at a certain weight, will fail to give more than a rough equality. Also the state of the atmosphere and the shape and diameter of the mould makes a difference, as does also the size of the grains in the case of gunpowder.

Although gunpowder can bear a great pressure without injury, yet it is not advisable to do too much in this direction, as it is very easy to get local overheating by the presence of a foreign particle or a hard grain. Also the more powder is compressed, the more it will adhere to the mould, and in pushing out the cartridge a greater pressure will be required. It is the friction thus caused which produces the greatest heat, and where the most danger exists. When, therefore, a number of moulds are not equally charged, and they are all compressed by pistons fixed on a common head, the cartridge which contains most of the powder, may, at a certain stage, receive all the pressure intended for the lot, and will, in any case, get more than its share. Hence the necessity of an arrangement to prevent an excess of pressure. This can be done by weighted levers on the bottom pistons, or, much better and simpler still, by keeping each mould independent and moveable.

The same applies to hydraulic presses. Most of them have one ram only, so that the cartridge, which may vary from $1\frac{1}{2}$ to 3 inches in height, is far more compressed on the bottom than on the top. Those with one ram on top and bottom make a better compression, and want less pressure on either side, but they are costly and cumbersome. In neither of them, as a rule, is any arrangement to prevent an

excess of pressure provided, and the best means of doing this is the movable mould.

Presses for prismatic powder, where needles of phosphor-bronze enter the moulds, require careful inspection, as the slightest bend of a needle can cause leakage.

Another method of powder manufacture may be briefly mentioned, which was long ago known to the Tartars, and some nine years ago practised in this country. This method is to dissolve the saltpetre in hot water, add the other ingredients, and boil down the whole with constant stirring during the evaporation. The English system of inspection would have soon put a stop to the way in which this was done for some time on the Continent, where this process was carried out in a kind of washing copper with a coal fire underneath, and where the contents of the copper sometimes went off through part of the powder being caked at the bottom and excessively heated.

The manufacture of cocoa-powder does not differ from that of ordinary gunpowder except in the preparation of the charcoal, which is no more dangerous than the work of a rag boiler.

In connexion with gunpowder may be mentioned also the manufacture of safety fuses. This presents no particular danger, except that in spinning the first layers of the fuse, where a fine stream of powder falls in as the fuse is formed, the excess of powder falls on the floor covering a large area, requiring precautions to be taken against friction or the fall of the weight which keeps the fuse stretched.

Nitro-compounds.

The next group to be dealt with are the so-called nitro-compounds or chemical explosives. These are produced on a very large scale, and gain daily in importance; but their manufacture involves generally a great amount of machinery and apparatus, and the knowledge of all the accompanying circumstances is still far from being perfect, besides being sometimes of a very complicated chemical character.

Nitro-compounds are liable to explode at a lower temperature, are more sensitive to concussion and friction than gunpowder, and in addition, as products of chemical action, are liable, under unfavourable circumstances, to undergo chemical changes which may render them unstable.

A nitro-compound is generally formed by the action of nitric acid on a hydrocarbon, sulphuric acid being added in order to take up the water formed during the process and to keep the nitric acid as far as possible at its original strength, so as to avoid the formation of lower nitro-compounds, which would either reduce the force of the explosive, or even render it unstable.

Comparatively the least dangerous to manufacture are gun-cotton and collodion cotton. With the exception of the nitration and the compression into cartridges, the whole process is worked with a large excess of water, and although it is quite conceivable that a particle of gun-cotton surrounded by water may explode when struck by a heavy weight, yet such a case is hardly likely ever to occur.

The cotton has to be very carefully purified from resinous matter and soluble substances, as they would form unstable by-products if allowed to remain. This is usually effected by boiling the cotton in a solution of soda. The nitration is done in England by dipping the cotton into the mixture of nitric and sulphuric acids, which are contained in a cast-iron vessel, squeezing it roughly out on a grid, and then letting the nitration complete in earthenware pots, which stand in running water. On the Continent they employ nitrating machines, consisting of a cast-iron vessel with a lid screwed on, having a false bottom which can be moved by means of a screw passing through the lid. The cotton remains in the machine during two hours, and then the false bottom is lifted towards the lid, thus squeezing the cotton out. In another factory suction is applied underneath the false bottom to drain the cotton.

The nitrated cotton is further deprived of the bulk of its acid by treatment in a centrifugal machine, whence it is passed as quickly as possible into a washing machine.

Care has to be taken that the acid cotton remains constantly under the acid or the water, or at least well covered, else, as it absorbs moisture rapidly, it decomposes, and once

a decomposition is started it is almost impossible to stop it. This decomposition is attended by large volumes of red fumes, and sufficient means of ventilation and escape for such have to be provided from the outset in case they are formed. The warmer the mixture, and the less liquid acid it contains, of course the more liable it is to decomposition, hence it is on warm and moist days centrifugal machines are most liable to fire; this seldom happens in the winter, unless some water, oil, or other foreign material falls into it.

Once it is immersed in the washing machine, whose water has to be constantly changed, the gun-cotton is no longer subject to sudden decompositions during the subsequent processes of manufacture, but the acid still remaining in it has to be eliminated with the greatest care, or else a gradual decomposition will take place. I will not detail this manufacture, as it is well known; suffice it to say that gun-cotton, which stands the English Government's heat tests, is quite safe under all ordinary circumstances.

The compression of gun-cotton into cartridges requires far more care than that of gunpowder, as this is done in a warm state, and gun-cotton, even when cold, is more sensitive than gunpowder. When coming out of the centrifugal machines the gun-cotton should always pass first through a sieve, in order to detect nails or matches, which may by chance have got into it. What has been said as to gunpowder presses applies still more to those for gun-cotton, although the latter are always hydraulic presses. Generally the pistons fit the mould perfectly, that is to say, they make aspiration like the piston of a pump. But there is no metal as yet known which for any length of time will stand the constant friction of compression, and after some time the mould will be wider in that part where the greatest compression takes place. The best metal for this purpose has proved to be a special steel made by Krupp, but this also is only relatively better; for pistons I prefer hard cast iron. If the position of the moulds and the pistons is not exactly the same in all cases, what the Germans call "Ecken" (English, "binding") will take place, viz., the mould will stand obliquely to the piston, and a dangerous friction will result.

For certain purposes, such as torpedoes, engineers' cartridges, &c., the gun-cotton has to be turned in a lathe, or drilled or planed. This should always be done under a constant stream of water, to keep the tool cool, as well as the gun-cotton in contact with it.

Of course, it is necessary to protect the man working the hydraulic valves during compression. At Waltham Abbey they have a certain made of ships' bawlers, which is at the same time elastic and resistant. The author has found from experience that a partition wall 12 inches thick, made of 2-inch planks, and filled with ground cinders, gives very effective protection. There are scarcely ever more than 5 lb. of gun-cotton under pressure at the same time, and in the case of an explosion the parts projected embed themselves in the cinders. There is a door in this partition to get to the press, and a conical tube penetrates the wall, which enables the man to see the whole work from a safe standpoint. The roof or one side of the building should be made of glass, so as to give the explosion a direction, and as a matter of fact it will not injure the walls of the building, even if they are only one brick thick.

The drying of gun-cotton is no less attended with risks, if it is done by improperly constructed arrangements. It is generally accepted that the drying should not take place at a higher temperature than 104° F. To secure this an electric alarm thermometer should be provided. If a current of hot air passes over a layer of gun-cotton, the cotton becomes electrified, and most, if not all, the fires in gun-cotton drying-houses are due, in the author's opinion, to a neglect to carry away this electricity.

I am indebted to Mr. Walter F. Reid, F.C.S., for much information in this respect. He was the first, so far as the author knows, to make metal frames, carriers, and sieves, upon which is secured the cloth holding the gun-cotton, and to earth them.

In drying houses there is a large amount of gun-cotton dust produced, which deposits on walls, floors—in fact everywhere. This dust, being warm, is very sensitive to friction;

in fact, Colonel Cundill once told me that even the hard friction with a felt shoe has been known to fire it. The workers in these rooms should therefore always wear felt shoes or go barefooted, avoid all unnecessary friction, and frequently wash the floors and walls. The floor should be covered either with india-rubber or linoleum.

On no account should an exposed metal pipe for the conveyance of heat be allowed in the drying room. Although the heat may not exceed 104° , and the radiation of the pipe may be sufficient, yet there might be a more sheltered place, such as a bend, a corner near a wall &c. where the quantity of heat is accumulated, and a far higher temperature reached, than that of the air entering, and it is just such places that will be filled with cotton dust, which itself will serve as an accumulator of heat. An accidental blow on the metal pipe may also happen, so that it is best to exclude them altogether from the room.

The above remarks about gun-cotton apply to mixtures of nitrate and gun-cotton, such as tonite, potentite, &c.

The manufacture of nitro-glycerin and dynamite is by outsiders generally considered as an extremely dangerous one, and it certainly is in the hands of untrained and inexperienced people; but if conducted by experts it is far less risky than the manufacture of gunpowder. Still, as it is essentially a chemical operation, its safety will always depend upon the amount of care bestowed on it by the workpeople; it requires a great deal of supervision to be always on the watch for neglect of duty.

The sources of danger arising from the raw materials will first be considered. The nitric acid used should be reasonably free from nitric peroxide. Opinions differ as to what is a reasonable amount, and no doubt the heat developed during the process of nitration is increased by the presence of this, a large amount of hyponitric acid; and, if sufficient care be not taken, may cause decomposition and explosion. Some say it should not contain more than 1 per cent., but some of the most perfectly conducted factories use it with even more than 4 per cent. The author's experience has been, that nitric peroxide undoubtedly produces more heat by its great oxidising power, but as the temperature of the mixture is always kept under about 77° F., it means that the nitration will last longer, because the workman must allow less glycerin to run in, and consequently he is expected to be still more attentive. Hyponitric acid also reduces the yield of nitroglycerin considerably. As a rule, those factories which buy their nitric acid insist upon having as little hyponitric acid as possible, sometimes below half a per cent. and those which make their own acid are not particular about 1 per cent. more or less. If the process of nitric acid making is conducted in such a way that a minimum of hyponitric acid be present, it will be difficult to have more than 93 per cent. pure monohydrate, and a large quantity of weak acid will result. If highly concentrated acid only is made, containing 95 to 96 per cent. pure monohydrate, then more heat has to be applied, which will always decompose some nitric acid into hyponitric acid. Of course a high percentage of monohydrate and no weak acid are most to be desired, because the first gives infinitely better results, whilst the latter is of little value, and if, therefore, the hyponitric acid should be eliminated, then a costly and tedious process of bleaching is necessary. This is the reason why a dynamite factory which makes its own nitric acid has never been known to have less than 2 per cent. of hyponitric acid as an average, but some even as much as 7 per cent. A new process which the author has recently invented gives invariably less than 1 per cent. of hyponitric acid with from 95 to 96 per cent. pure monohydrate, and this is now being rapidly introduced into many factories. This process can even be worked in such a way that the acid will not contain more than one-tenth of a per cent. of hyponitric acid, and acid, with even as much as 99.40 per cent. pure monohydrate, has been made by this process. This is the strongest acid ever manufactured on a large scale, but there is a great amount of the possible yield lost. It may, therefore, be said, that unless the nitric acid is after its manufacture submitted to a long and expensive bleaching, the best which can be made on a commercial scale will always contain about 1 per cent. of hyponitric acid. As it is scarcely to be expected that

everybody can have the very best acid, the limit of hyponitric acid may be set at 2 per cent., which does not increase materially the danger of too much heat being developed. Beyond this limit the heat of the mixture may rapidly increase, and the workmen has to be constantly on the alert to shut off the inflow of glycerin, or to apply more vigorous cooling and stirring. As it is desirable that every process should depend as little as possible on the attention of the workmen for avoiding accidents, an excess of hyponitric acid should not be allowed.

Sulphuric acid and glycerin are nowadays made very pure. Arsenic may be in both, especially in the sulphuric acid, but it should never be allowed to exceed one-tenth per cent. on account of the well-known strong oxidising action of arsenious acid.

Glycerin is a very intricate substance, so far as its use for making nitroglycerin is concerned. Of course a large amount of organic matter, such as cellular substances from the tissue or fatty acids are both objectionable, as they form unstable compounds during nitration. The presence of chlorine also has to be avoided, because it will ultimately form hyponitric acid. But even if the glycerin is nearly perfectly pure, and contains nothing whatever but about 0.15 per cent. of total residue, organic and inorganic, it will sometimes happen, that the nitroglycerin made is full of a bulky, flocculent matter, which prevents its separation from the acids for a very long time. This only happens with glycerin of a special manufacture, and up to now even so high an authority as Mr. Otto Helmer has been unable to find out to what component or impurity this is due.

The operations of nitrating and separating the nitroglycerin do not require more attention than that the temperature should not even at the finish exceed 86° . I do not refer by this to the Bontny-Fancher process, which in itself had a special source of danger, inasmuch as in it the sulphuric acid was first allowed to act upon the glycerin, which caused the organic impurities to become charred, and to form minutely suspended carbon particles. This prevented the nitric acid, at its highest concentration, penetrating every particle of glycerin, and sometimes prolonged the separation for days. It will be explained later on why this must have been dangerous, or is still so as the process is still said to be used on a small scale at the French Government factory at Vonges.

It is in the apparatuses used for nitration and separation that the chief danger lies on account of their construction. The nitrating apparatus is now generally a large lead tank, with a number of cooling worms, through which cold water runs. The tanks are closed at the top with suitable openings for the admission of glycerin and compressed air, for the escape of the fumes and for the constant control of the temperature, also for discharging the tank either into the separating apparatus or into a drowning tank. All these arrangements of course complicate the nitrating apparatus, and require constant attention. A detailed description of the different apparatuses in use cannot be given in this paper, as it would be sufficient for a paper by itself, but some of the chief sources of danger, however, must be pointed out. First is the lead itself usually used in the construction. The combined action of nitric, nitrous and sulphuric acids on the lead is very great; but still greater is that of the fumes, when mixed with the outside air, because diluted acid attacks metals more than strong acid. The lead should be perfectly pure, some even prefer remelted old lead, as it becomes harder by remelting. If the slightest amount of zinc is present the lead is very soon perfectly honeycombed. The fumes should be drawn off through a pipe with a good draught in it, so that the outer air cannot enter the vessel. The compressed air used for stirring and cooling should come from a storage vessel, where it can deposit all its moisture, and the pipes leading to the apparatus should ascend as much as possible, and have a drain tap attached. All joints should be made quite tight, and the construction of the cooling worms must be well understood, as they will expand and contract, and can easily leak. It must be understood that the slightest leak of a water pipe may start a very serious decomposition, and it is therefore a good plan to test the whole apparatus every morning before starting work.

The manner of introducing the glycerin is another matter for consideration. In some apparatuses where a screw paddle assists the stirring, the glycerin runs on a disc attached to it, and is therefore scattered by centrifugal force in minute drops. Sometimes a perforated pipe supplies the glycerin, and very often an injector. Those injectors, which are placed near the bottom of the vessel, are soon eaten away, and sometime cause a sudden inrush of glycerin, which is of course to be avoided. Injectors or pressure vessels, which blow the glycerin through a pipe, are perhaps the best.

The temperature in the apparatus must be efficiently controlled; it is not sufficient to know the temperature of one part of the vessel only, since decomposition generally starts locally, and then spreads over the whole mass.

The taps for discharging to the separators and to the safety tanks want very careful fixing, and it is commonly said that it is a knowledge by itself to make all the different kinds of mastic or cements that are required in a dynamite factory. Of course the taps must not be placed so that water can get into them. At the same time much depends upon what pressure there is on the tap, and one of the objections to those huge American apparatuses is that they have a column of acid 10 or more feet high resting on the taps, or like 8 lb. pressure per square inch. It is so easy to get a tap or a plug knocked out, apart from the pressure on the tank and the enormous weight of the cooling worms.

The apparatus should of course be made so as to empty itself to the last drop, and the safety tap should be sufficiently large to empty the vessel in a few minutes.

Exactly the same remarks apply to the first separators and the bottles used in the secondary separation.

It might be appropriate to mention here, that a decomposition in a properly constructed apparatus is a very rare occurrence indeed, and due only to leakage, bad glycerin, or inattention on the part of workmen. Even if a decomposition should be seen starting, there is no need to drown a charge at once, or to lose one's head and run away. A decomposition, as has been mentioned, begins at one point, and spreads gradually through the whole mass. A slight decomposition will develop a huge volume of dark red fumes, and is certainly alarming to the novice, but it will take sometimes 10 or more minutes before it can develop into an explosion. The author has seen decomposing charges entirely saved by the coolness of the workmen, who freely used all the available means for cooling and stirring. In one instance, the acid underneath the nitroglycerin in a separator decomposed, and the man in charge, who was a new hand, in his confusion opened the nitroglycerin tap instead of the safety tap, and although the whole of the nitroglycerin had time to run into a water tank, it was more than a quarter of an hour before one could think of entering the building to drown the decomposing acid.

In the process for separating the nitroglycerin from the acids, there is the danger of a prolonged contact of the two liquids, which has been fully investigated by the Home Office in reference to the Pembrey accident. Nitroglycerin dissolves in sulphuric acid, and just at the line of contact between the two liquids many of those lower nitro-compounds collect which have been formed from the impurities in the glycerin. Others collect on the top of the nitroglycerin, where they are exposed to the action of the air. Pure nitroglycerin can remain a very long time in contact with pure nitric and sulphuric acid without alteration; but in a process where everything is impure, the lower nitro-compounds are soluble and unstable, and therefore the separation should be finished as quickly as possible. I have referred already to the glycerin retarding the separation, but there are also mechanical impurities in the other reagents which have even worse effect. If the sulphuric acid contain much lead, if the mixed acids have been in the storage tanks too long, and some lead or iron is dissolved in them, this will be suspended in minute, but bulky quantities in the mixture of nitroglycerin and acids which leaves the nitrating apparatus. Still more marked is this effect in the case of any carbonaceous matter introduced, such as straw from the carboys, gross organic impurities of the glycerin, &c. This is the case with the

Boutmy-Faucher process where by dissolving the glycerin in sulphuric acid, the impurities in the former are charred, and delay the separation in an extraordinary way. The worst case known to the author was one, when a second-hand air vessel was bought for the storage of sulphuric acid and a thick layer of rust prevented it being seen that the vessel had formerly been coated inside with tar. The sulphuric acid became quite black from the tar, and after two days' separation only half of the nitroglycerin could be recovered.

It must be understood that the difference of specific gravity between the nitroglycerin and the refuse acids is only 0.100, the former having a gravity of exactly 1.600 and the latter about 1.700, and although the greater fluidity of the acids facilitates to a great extent the separation, yet such bulky impurities remain for a long time suspended and form contact between the more sticky nitroglycerin and the acids, thus obstructing separation.

The secondary separator receives the spent acids, which generally contain minute globules of nitroglycerin in suspension, and it is essential that they should have time to separate. This secondary separation is the weakest spot in a dynamite factory. The fact that small quantities of highly acid nitroglycerin are floating on the top of strong acid, and, even with the best ventilating tubes, are exposed to the air, may account for some decompositions, but the author believes that a careful investigation of all the facts would nearly in every case point to another cause for an accident, and that cause either a leak of a water pipe or the intrusion of some organic matter.

Some experiments which the author has carried out with waste acids have shown that if *large* quantities of glycerin are poured into waste acid (which has nearly invariably the composition of about 10 nitric monohydrate, 70 sulphuric monohydrate and 20 water) a turbulent decomposition takes place in a very short time. If we take the process of nitration to consist of an interchange between the NO_2 group of the nitric acid and the hydrogen molecules of the glycerin until complete exhaustion of the former, then every particle of glycerin entering in excess will not be nitrated, but dissolved in the sulphuric acid, as after the formation of the bulk of nitroglycerin the nitric acid left occupies only about one-fourteenth of the whole mixture, and in spite of violent stirring it is difficult to cause the little nitric acid remaining to come in contact with the glycerin particles. Besides, this nitric acid, as it is seen from the composition of the refuse acids, is in a very diluted state, and if it could easily come in contact with the glycerin, it would only form mono- and dinitroglycerin, which are soluble. Thus it will be seen, that an excess of glycerin forms a very dangerous mixture, and on two occasions at least the cause of decompositions could be distinctly traced by the author to such an excess.

It must be pointed out that a small excess of glycerin may happen with any operation, as it is impossible to calculate exactly the quantity required, and a slight variation in the strength of the nitric acid will at once alter the quantity of glycerin, which can be converted into trinitroglycerin.

This is another reason why very strong acid with a rather higher percentage of nitrous acid is preferable to the reverse as the workman can guard against overheating, but he has no means of ascertaining the total nitrating capacity of the nitric acid. But a small excess of glycerin, although just affording the amount of danger connected with the work, is still not a distinct danger, so long as proper attention is paid. It is only a large excess which can produce a *sudden* decomposition, and it would be impossible to stop this. This excess of glycerin need not necessarily be the consequence of an error in weighing, it can also be brought about by using too weak nitric or sulphuric acid, or by a mistake in weighing the acids for mixing. The only remedy in this case is to watch the yield of nitroglycerin. If it falls below a certain limit, then part of the glycerin must have escaped nitration, and the only plan to adopt is to at once drown the waste acids, as containing too much glycerin. With good yields of nitroglycerin and proper attention the secondary separation never gives any trouble.

As the waste acids are in most cases treated in a denitrating apparatus to recover the two component acids separately, care must be taken that every particle of nitroglycerin is removed in the storage tanks before working them up. Small drops may come up after days, and an explosion of a denitrating plant in Italy was due to neglect in this direction. The storage tanks must also be protected against the weather, and have a safety tank attached, as their contents will sometimes decompose, especially in hot climates.

In the operation of washing and filtering the nitroglycerin warm water should be used with caution, as nitroglycerine begins to evaporate at 101°, and the inhalation of nitroglycerin vapours in larger quantities is injurious.

The other operations do not require more attention than with other explosives, except the formation of cartridges by lever presses, where the material falls through a funnel into a tube, and a piston on a lever forces the dynamite out in the form of a cylindrical mass. There are two kinds of presses, one where the parchment paper is wrapped round the tube, and the whole cartridge is made in one pressing, and others where the dynamite is pressed out by consecutive strokes with the lever, so that a continuous string comes out of the tube. This is broken off when it reached the required length, and then wrapped round with parchment paper. This kind of intermittent pressing is no doubt the best, and the single stroke presses are rightly objected to by the German industrial inspectors. It is patent that in order to press out a cylinder of soft material of about four inches in length, there is perhaps twenty times more force wanted than for a piece of an inch and any metal or grit particle or even a hard lump of kieselguhr may produce enough friction on the tube to cause an explosion. By far the majority of the explosions in cartridge hnts happened with single stroke presses.

Of course cartridge presses must be so constructed and secured as to prevent any hard blow or friction.

The manufacture of blasting gelatin, gelatin dynamite, and gelignite calls for very few remarks. As the process is carried out with the aid of artificial heating, care must be taken to avoid excessive heating, since the collodion-cotton may begin to decompose, and the nitroglycerin to evaporate. The machines for mixing, if such are used, and for making cartridges must be so constructed as to avoid undue friction, and to allow of ready inspection and cleaning.

The danger of freezing has still to be dealt with. It is well known that nitroglycerin freezes at about 46° F. Dynamite and blasting gelatin will freeze at slightly lower temperatures. Numerous experiments have shown that frozen nitroglycerin and dynamite are highly insensible against shock, and that even a bullet fired from a military rifle at 50 paces has failed to explode in, whereas soft dynamite explodes readily at 300 and more paces. Yet somehow frozen nitroglycerine *does* sometimes explode. To the author's own knowledge the removing of some frozen nitroglycerin from the ground by means of a pick-axe, the sudden turning of an earthenware tap, around whose plug some nitroglycerin froze, the cleaning of vessels containing frozen refuse, and even the forcible breaking of a frozen dynamite cartridge, have resulted in explosions, and it is probable that similar instances are known to others. The author believes that the explosion of frozen nitroglycerin is due to a sudden alteration in the molecular arrangement of the frozen nitroglycerin—such as Professor Tyndall stated in the case of ice—and the consequent production of vibrations sufficiently high to cause a detonation. This is certainly a striking illustration of the fact, that explosion is not merely a result of heat.

Blasting gelatin and the gelatin dynamites, on the other hand, are extremely sensitive in a frozen state, which is solely due to the collodion cotton. In the soft gelatinous state of course every shock is annihilated, and the gelatins are in fact indifferent in this state; but when the gelatin is frozen, and forms one rigid, hard mass, a blow will be readily communicated throughout the whole mass, and the collodion cotton will be the first to

explode. It is therefore of high importance that the nitroglycerin or dynamite should never be allowed to freeze during manufacture. Even in moderately warm rooms the cold earthenware taps may cause freezing, or drops of nitroglycerin spilt on the floor may become hard, and the danger of working frozen dynamite in cartridge presses is very great. It has repeatedly happened that small crystals of frozen nitroglycerin "cracked" on a wooden floor by being rubbed with a leather shoe.

The sun has a decided effect on the nitroglycerin, inasmuch as the heat generated will decompose it. This is the reason why the roofs and windows should be painted white; especially the window panes, as they will usually contain some faulty spots, which act like lenses. The action of the sun on nitroglycerin that had been inadvertently allowed to run away in the sand has several times produced explosions.

The refuse resulting from the sweepings, the residues on the filters, the mud in the deposit of washings, &c. have to be carefully burned. This refuse, or even defective dynamite, if laid out in a train, and ignited, will burn quietly for some time, but then suddenly explode. The author is indebted to Dr. Dupré, F.R.S., for the hint, that by pouring paraffin oil over such refuse it can be burnt without fear of explosion.

Although all the possibilities of danger have not been mentioned, and although perhaps the long list may have alarmed you, yet the author confidently asserts, from personal knowledge and long experience, that the manufacture of dynamite is far less dangerous and certainly less subject to sudden and unforeseen accidents than that of gunpowder, which has a record of casualties for more than five centuries.

Smokeless Powder.

The manufacture of smokeless powder has within the last four years come to the foreground, and is in many instances similar to that of the gelatin-compounds. As it is a comparatively new industry, chiefly in the hands of Governments, and as none of the powders can yet claim to have reached the stage of perfection, it may seem to be superfluous to enter into many details. The fact that nearly every factory has some process of its own, because everyone is anxious to keep its own experiences secret, makes general remarks very difficult.

Smokeless powders are practically of two kinds, those made from gun-cotton and a solvent only, and those made from nitroglycerin and gun-cotton with or without the aid of a solvent. Of late nitrated starch seems to be favoured. As a solvent acetone is now generally used, and the process of dissolving the gun-cotton, or making a gelatin of nitroglycerin and soluble gun-cotton, with or without the subsequent addition of insoluble gun-cotton and camphor, does not want any special allusion, as the machines for incorporating the materials are about the same as now used for the manufacture of blasting gelatin. But the subsequent working up into small square sheets or round discs, in imitation of the manufacture of certain pastries, requires more attention, although it must be said that the acetone, of which traces always remain in the powder, renders it comparatively safe. The jelly-like incorporated mass, when leaving the mixing machine, is subjected to a partial evaporation, and then passes through steam-heated rollers to be rolled into sheets, and at the same time to evaporate all the acetone. In these rollers small local explosions sometimes take place which are probably due to some undissolved gun-cotton being submitted to heat and friction, but which pass away without doing any harm. Great care has to be taken to collect the acetone vapours, as they are explosive and may spread over a large area. The cutting of these sheets into small squares is also without special risk, as the pressure on the sheet is small, and no undue friction is likely to occur. Of course, the powder should not be allowed to accumulate, as although considerable quantities of it can burn without explosion, yet the fire spreads quick enough to cut off escape, as has been proved at a fire in an Italian factory. The manufacture of cordite, the British smokeless powder, varies in some stages from that of others, and being the invention of Sir Frederick

Abel, and manufactured under his superintendence, does not call for further remark in this paper on the dangers of explosives.

The stability of smokeless powders with regard to atmospheric and climatic influence have still to be conclusively tested.

Other Explosives.

Nitrobenzene is, I believe, no longer used with explosives; its manufacture is well known, and is only dangerous during the nitration and through the poisonous effects of its fumes.

The manufacture of picric acid is also to a certain extent outside the scope of this paper. It presents no danger during the manufacture proper, but the finished product, when mixed accidentally with certain materials as lime, nitrate of lead, &c., will produce a detonating mixture, as has been successfully proved by Colonel Majendie and Dr. Dupré in their report about an explosion in Manchester.

Under the name of "Melinite," "Lyddite," "Ecrasite," &c., picric acid has been used for filling shells. Picrate of ammonia, trinitroresol and the ammonia salt of it are also used. They are melted in a hot water-bath and filled into the shells. They are exploded generally by a primer of gun-cotton. As this work is only carried out in military establishments, further consideration is not necessary before this Society. Neither is it necessary to enter into the details of manufacture of roborite, secunite, ammonite and similar products, or fireworks. The processes used with the former are very much the same as those used in other manufactories of explosives. In the manufacture of fireworks the preparation of the different mixtures, the compression into rockets, the distribution of pills for amorces, &c., can with little modifications be governed by the considerations applicable to gunpowder factories. Only the frequent use of chlorates, especially Chertier's copper, calls for attention as the cause of many decompositions, and all chlorate mixtures are extremely sensitive to shock and friction. Of course, if the mixture is moistened to form a paste, it will stand a great amount of shock, but when too much water is added, some particles may become exposed to the direct action of the blow.

The last explosive to be mentioned, before discussing the dangers in conveyance and use, is fulminate of mercury, which is used for filling caps and detonators. The manufacture is simple enough, and with ordinary precaution no accident should happen. Of course the ebullition after the addition of alcohol has to be carefully regulated, and attention has to be paid to the way how the developing vessels are carried about, the fume pipes put on, &c.; the nitrous ether formed should also be condensed away from fire. The washing of the fulminate should be well attended to, to avoid decompositions, and the ready-made fulminate should be stored with not less than 20 per cent. moisture. It is chiefly in the working up of the fulminate where the danger comes in. As to drying it, the ordinary precautions as to heating by a current of air, absence of metal in the room, having hair rugs or india-rubber mats on the floor are sufficient. The mixing of the fulminate with nitrates, chlorates, ground glass, &c., is perhaps the most dangerous part, as thereby a large amount of friction is produced. The process used at Woolwich is certainly the safest, and will give a better mixture than the usual work with a feather. It consists essentially of a silk bag on which there are diagonally placed india-rubber discs, like a string of pearls. To the bottom of this bag is fastened a thread, which is moved by a lever from behind an iron screen, thereby taking up and throwing down the fulminate between the discs. No explosion has happened at Woolwich since the introduction of this ingenious mechanism some years ago.

The filling of caps with the fulminate is done everywhere by carefully planned machines, which avoid friction and over-charging. The compression of the priming composition is best made in moulds attached to separate weighted levers for each cap, so that in spite of the probable inequality of filling, each charge should only receive the same pressure as the other. In some factories the whole press is sheltered

by a screen which is automatically closed during the compression, and no composition is allowed to be in the room.

In fulminate factories proper precautions must be taken against any possible friction. These are briefly the use of hair rugs, felt slippers, frequent washing and dusting of floors and rugs, preventives against spilling of material, &c. Like other mercury substances fulminate is injurious to the body, especially the gums of the teeth, if too much dust is produced and the ventilation not efficient.

The other dangers to be attended to in connexion with the manufacture of explosives are those which arise from the general arrangement in the factories.

This is the only country, to the author's knowledge, in which the exclusion of iron from the interior of the buildings, the absence of so much as a few grains of mud or grit on a floor, and in general the cleanliness throughout are rigorously enforced. It certainly made a great stir amongst the manufacturers when the Explosives Act came into operation, but seldom was there on the whole a wiser measure taken. If one remembers that last year only in one gunpowder factory were there fatal accidents, and that the mortality amongst the workmen in explosive factories was not larger than that in all London, you will agree with the author that the Explosives Act was very beneficial and that the inspectors who carry it out are doing most useful work. It is certainly not the absence of a little grit, because in thousands of cases it will be of no harm, but the general spirit of order, cleanliness and precaution instilled to the workmen which makes a factory safe.

According to the Explosives Act, every danger building must be provided with an efficient lightning conductor. In spite of the Lightning Rod Conference, in which so many eminent men took part, the question as to what forms an efficient lightning conductor in a factory for explosives is not yet definitively agreed upon. There can be no doubt that a lightning conductor is a good and useful instrument on a dwelling-house where an accidental disturbance in the arrangement may not do great harm, but the case is entirely different with a workshop or magazine for explosives. The thorough and reliable examination of a lightning conductor can only be done by an electrical expert, and in a factory where sometimes 100 of them have to be tested this takes several days. Yet, if a gale is blowing, or the factory is exposed to the influence of sea-atmosphere, the lightning conductor is soon out of order again. Then take the presence of machinery in the buildings, tram-lines, pipe-lines overhead and underground, and you will find that a lightning conductor is not only a very limited preventive, but very often a positive danger. Without further entering into this question the author thinks that a competent investigation of this subject with reference to explosive factories would be very beneficial.

A great many factories are now lit by electricity. Since this paper was written, special regulations in regard to electric lighting in explosive works have been issued by the Home Office. I do not wish to criticise these regulations, as too short a time has elapsed, and their effect cannot yet be appreciated. I will therefore only give my own experience. It is highly important that suitable lightning conductors should be attached to the circuit. From experience, the author knows of two cases where the lightning struck into the wires, which were carried overhead. The wires should always enter a building from opposite sides, so as to prevent accidental short circuits, and no joint or switch should be allowed inside the building. The lamps should invariably be surrounded by a tightly fitting large glass globe, which allows sufficient radiation of the heat. Although the heat on the outside of a lamp is scarcely larger than 120°, yet, if a lamp be covered with explosive dust, and the heat cannot radiate into the open air, there will be such an accumulation of heat that serious accidents may occur. As to an excess of tension in the current the best plan is to have an arrangement whereby, in case the tension rises over a certain limit, the whole of the plant is cut out of circuit. It is by far preferable to have the place in darkness than to see sparks travelling along the wires.

It would be quite impossible to write a paper by itself about the dangers in connexion with the use of explosives

in mines. Miners will frequently insist upon treating explosives with the greatest recklessness, and if it were not as a rule accompanied by a loss of life or limbs, it would be able to write quite an amusing paper about the innumerable ways in which the miners handle explosives. Carrying gunpowder in open boxes, with a candle on the hat or in the hand, squeezing detonators with the teeth, charging boreholes with boring bars, thawing dynamite on a hot stove, or even on an open fire, in a straw hat, are cases that frequently occur. It will still take a long time before anything like proper precaution will be taken everywhere.

The carriage of explosives, whether by road, vessel, or rail, is under ordinary circumstances free from danger. No explosive is licensed which does not in itself present a certain degree of safety, and the packing is so substantial that unless the packages are very roughly handled not even a spilling of explosive is likely to occur. For this reason, in almost every country the carriage of explosives by rail is allowed. Of the more important countries Great Britain alone makes an exception as regards gun-cotton and dynamite, but why cannot be said. The railways will carry gunpowder, detonators, blasting gelatin and gelatin dynamite, but not gun-cotton and dynamite. Gun-cotton is always sent with from 20 to 30 per cent. moisture, in which state it cannot be exploded by ordinary means. Dynamite is no more dangerous than gelatin dynamite, and in the 20 years during which it has been carried on Austrian railways not a single accident has occurred. Let us hope, that here also this obstacle will soon be removed; it injures the railways indirectly more than anybody else, as they are the largest consumers of coal and iron, which cannot be won without the use of explosives.

DISCUSSION.

Mr. ARNOLD PHILIP said that some 18 months previously in going over a large dynamite works, he had seen a plant employed for the recovery of the acids which had been used in the manufacture of the nitroglycerin. This apparatus consisted in part of two scrubber towers apparently built of flags of sandstone held together outside by iron tie-rods; inside they contained coke or some other suitable material on which to condense the acid fumes. The waste acids were heated in stills connected with the scrubbers; there was, however, some difficulty in employing this apparatus, for explosions were not infrequent. These explosions were usually slight in character, and chiefly occurred in the scrubbers, but they caused considerable financial loss by the damage which they caused to this part of the plant. All the trouble was due to the minute amount of nitroglycerin which remained in the waste acids even after they had been allowed to stand and settle for a very considerable time. On account of this difficulty there was a natural disinclination on the part of the manufacturers to distil waste acid, and it was not at all an uncommon thing in nitroglycerin factories for tons of it to be thrown away. If, however, these traces of nitroglycerin could be satisfactorily removed, the acids might afterwards be safely recovered, and a great saving thus introduced. It was possible that this might be done by dissolving out the trace of nitroglycerin by means of paraffin. Of course the strength of the acids in question made it quite impossible to employ either hydrocarbons of the benzene series or ether for this purpose. With regard to the question of lightning conductors, it would be interesting to know whether Mr. Guttman had had any experience with Professor Oliver Lodge's method of protecting buildings; this was based on the same principle on which electrometers were sometimes shielded by wire cages. Professor Lodge proposed to cover buildings with what was practically a network of galvanised iron wire. This material was of course far cheaper than copper or any copper alloy, and although not so good a conductor, yet for electric discharges of such high potential as lightning, as long as there was a metallic conductor, it really mattered very little whether it had a high or low conductivity.

Mr. DE MOSENTHAL said that he believed that Dr. Duprè's experiment with the broom stick was correct only so far as chlorate of potash explosives were concerned. Referring to the question of lightning conductors, an explosion due to

lightning had occurred quite recently in a manufactory on the Continent, where the rod had been examined by an expert a few days only before the explosion occurred, and was therefore probably in perfect order. In that case the conductor was placed on the earth works which protected the building, but it was generally supposed that the position of the conductors was immaterial. As Mr. Guttman had pointed out, very little was known about the subject; and it was to be hoped that the report of a Special Commission which had been at work in Germany for something like two years, would throw further light on the subject.

Lieutenant-Col. CUNDILL remarked that last year only one fatal accident had occurred due to the manufacture of explosives. He thought that statement spoke volumes for the care exercised by the manufacturers. His Department was much indebted to the trade for the way in which any suggestions made by them before the Explosives Act came into force had been carried out. The average number of deaths in England and Wales alone caused by explosions in manufacture in the seven years preceding the introduction of the Act was 39.5, the average was now something under eight for the United Kingdom. In 1890 there were eight deaths, but those were all in one factory; and the accident which caused the one death in 1891, was due to a man hammering a cast-iron die-plate with a steel punch in a building where there was gunpowder, this being a flagrant violation of the statutory rules.

After some observations from Mr. OTTO HEHNER:

Mr. GUTTMANN in reply said that the suggestion of Mr. Philip to use paraffin for effecting the better separation of nitroglycerin from the waste acids, had not, to his knowledge, been tried with nitroglycerin, but it had been tried with picric acid. He knew of a case where it had been used for many years for separating the picric acid, but he had recently seen a sample of a compound which had been found during such separation, which was a dangerous one. He had been asked to make experiments with this substance as an explosive, but it smelt so decidedly acid, that he requested that it should be taken back as soon as possible and washed. He had carefully considered Professor Oliver Lodge's system of lightning conductors. The idea, however, was not new. A Belgian (Mr. Melsens) was the first to make lightning conductors in that manner. Professor Zenger of Prague had developed it, and it had been very extensively tried by the Austrian military authorities. In that country, in the mountain region of the Karst, a thunderstorm occurred nearly every day, and the lightning struck everything above ground. They had a number of exposed forts and military stores there, containing gunpowder, ammunition, ready-made shells, &c., and it was not a pleasant feeling to find these things exposed to such thunderstorms. They had tried the wire cage system and it was found to be a very effective protection. Col. Ph. Hess placed in such a cage one of the bridge detonators employed for military purposes, which are so sensitive that the smallest amount of electricity would fire them, and he could not get an explosion although he applied the sparks of a Wilmhurst machine. So far no more had been heard about the practical application of this system. As to Mr. de Mosenenthal's observations, he would just mention that the broom stick question had been discussed in that room by Dr. Duprè. If he remembered rightly it was in connexion with kinetic, an explosive which it had been attempted to introduce in this country. For a long time the English Government would not pass it, on the ground that it was not safe. This the agent of the firm who introduced the explosive tried, in that room, to explain was not the case. He remembered reading Dr. Duprè's speech on that occasion, in which he stated that everything in the hands of a man who was willing went all right, but that if any person who was not conversant with the matter struck the substance with a broom stick on a wooden floor it would go off. He believed that any explosive which Dr. Duprè had tested, did not fail to explode when struck with a broom stick. Lastly, he would deal with Mr. Hehner's observations. He (Mr. Guttman) had often discussed the question of glycerin with Mr. Hehner, and he was aware that Mr. Hehner held that a small quantity of chlorine, acid, or

aldehydes in glycerin was not very important; yet he believed he expressed the opinion of manufacturers when he stated that they held the opposite view. Mr. Hehner had said that experience was the principal thing to be taken into consideration, and the experience of manufacturers showed that the presence of chlorine developed hyponitric acid, a body, the formation of which they desired to avoid as much as possible. The same remarks applied to aldehydes and poly-glycerins. It was probably these constituents that formed the amount of organic matter in the residue. If 1 per cent. of organic matter was present in the residue, there was sure to be a smaller yield of nitro-glycerin, and a larger development of nitric peroxide.

the residue obtained was fused with hydrogen potassium sulphate. The mass was then dissolved in a dilute hydrochloric acid and the amount of alumina, lime, and magnesia determined.

RESULTS OF ANALYSIS EXPRESSED IN PERCENTAGE OF WEIGHT OF PAPER ANALYSED.

The calculations were made as follows:—

From the amount of alumina found the amount of potash alum present was calculated, and the sulphuric acid (SO₃) it would contain deducted from the total acid found. The amounts of sulphuric acid necessary to combine with the calcium oxide and magnesia found were also deducted from the total. We found in three cases out of four the amount of acid required to combine with all the bases was slightly deficient, possibly indicating the presence of a basic alum. In the case of the Imperial 140 lb., which we analysed twice with agreeing results, we can only suppose that there was an excess of alkali bases which we did not determine, as the paper and extract were basic to Congo paper. Although it is possible that alum, even when basic and present in small quantities, may act on certain colours, such as ultramarine, it would, in the absence of experimental data, be hazardous to express an opinion as to the nature and extent of such action.

THE ACID ACTION OF DRAWING PAPER OF DIFFERENT MAKES.

BY DR. P. NORMAN EVANS AND DR. QUIRIN WIRTZ.

In the proceedings of the Chemical Society of February 4, 1892 (Session 1891—1892, 20), an article appeared under the above heading by Professor W. N. Hartley, F.R.S.

On reading it we were surprised to find that the author had discovered free sulphuric acid in drawing papers manufactured by such celebrated makers as Whatman, Saunders, Hollingworths, and Arnold.

Papers of both old and recent manufacture are said to have contained free acid in spite of the well-known fact that the merest trace of free sulphuric acid will rapidly change cellulose into the brittle hydrocellulose, completely spoiling a paper containing it.

Professor Hartley further tries to trace the free acid to the souring of the materials after bleaching, and states that linen fibres,* even when steeped frequently in pure distilled water, persistently retain traces of free acid.

But how does such treatment as this compare with mill practice? This, as a rule, is somewhat as follows: after being soured with a little sulphuric acid the materials are circulated and washed with a large stream of hard spring water for about four hours, and thus any trace of acid that might otherwise be left in the fibres is neutralised. If we examine the reactions on which Professor Hartley bases his opinion that free acid is present in the papers that he examined; we find, as a well-known fact, that the two indicators, namely, litmus and helianthin, used by him show an acid reaction when brought in contact with pure potassium-alum. Now such alum is almost invariably used in sizing high-class papers with animal size, the object of its use, being to reduce the adhesiveness of the gelatine, on which also it acts as an antiseptic.

The question which we will next attempt to answer is this: Did not Professor Hartley mistake the alum reaction for that of free acid?

In order to answer this in a satisfactory manner we wrote to the manufacturers of Whatman's paper, and asked them to kindly send us some sheets of the same four qualities of paper as those which Professor Hartley had examined. These we tested as follows:—50 grms. of each of the papers was seven or eight times treated with boiling water until all soluble matter was extracted and no residue was left on evaporating a small quantity of the water. The extract so obtained was concentrated by evaporation and then made up with distilled water to 200 cc. Both the original dilute solution and the concentrated were found acid to litmus, but both were neutral to Congo red, which, as is well known, is unaffected by alum, but is turned blue by the smallest trace of free acid. As a further proof of the absence of free acid we determined the total sulphuric acid present in one portion of the concentrated extract, and evaporated another portion to dryness on the water-bath and

* The papers we examined contained more cotton than linen.

THE ACID ACTION OF DRAWING PAPERS.

BY C. F. CROSS AND E. J. BEVAN.

IN a recent communication to the Chemical Society (Proc. Chem. Soc. 1892, 19) Professor W. N. Hartley has called attention to the "acid action" of drawing papers. After examining representative specimens—chiefly "Whatman" papers—he arrives at the following conclusions:—

1. That the majority of papers of this class show an acid reaction. 2. That the acid reaction is due to the presence of free acid. 3. That this acid is sulphuric acid left in the "fibre" (rags) through imperfect washing after the process of souring. 4. That this conclusion from the results of analysis is supported by the observation of the difficulty of removing sulphuric acid from *linen* fibre by successive and exhaustive treatments with *pure* water.

It would occur to anyone familiar with the technology of paper-making that Professor Hartley was unaware that the details of manufacture render his conclusions in the highest degree improbable, and that therefore the evidence upon which they are based should have been proportionately unimpeachable.

To these conclusions, taken in order, we will oppose the results of our own experience in regard to these papers, which afford a much simpler and, *a priori*, more probable explanation of the acidity which Professor Hartley has observed.

1. The reactions of these papers, if and when acid to certain indicators, such as those employed by Professor Hartley, are *basic* to others, *e.g.*, methyl orange and Congo red. 2. That the apparent "acidity" is due to the presence of a *basic sulphate of alumina*, alum being an essential constituent of the mixture used in sizing these papers. 3. That in the making of the "Whatman" papers no free acid could survive the long process of washing of the soured rags. They are in fact treated for 3 to 4 hours in an "engine" with a continuous stream of the *exceptionally hard water* of the district (Maidstone). 4. In the "Whatman" papers *cotton* and not *linen* (flax) cellulose is the preponderating constituent.

To bring the matter, however, to a more direct experimental issue we procured samples of the following makes of "Whatman" paper, which were submitted to examination:—

1. Imperial.....	141 lb.	1891.
2. Imperial.....	72 lb.	1892.
3. Imperial.....	96 lb.	1892.
4. Double Elephant	133 lb.	1892.

These papers all showed a distinctly acid reaction with litmus and cochineal. The aqueous extracts from weighed quantities of the papers were titrated with standard alkali in presence of litmus as indicator; the results are given below, calculated to 100 grms. of the papers:—

1. Required to neutralise	1.3 cc. normal NaOH
2. " "	2.3 cc. "
3. " "	1.3 cc. "
4. " "	4.3 cc. "

With carefully neutralised solutions of *Congo red* and *methyl orange* on the other hand, the papers, as well as the aqueous extracts, gave a *distinctly basic* reaction.

Analysis of the aqueous extracts showed that they contained in each case a *basic sulphate of alumina*, and estimations of alumina showed that the quantities present were approximately in the ratio of the above results of titration.

Papers (1) and (4) were further treated with pure absolute alcohol. After evaporating the alcohol, the residues were treated with water, and the solutions, *basic* to *methyl orange*, were titrated with standard acid. Calculating the results on 100 grms. paper:—

1. Required to neutralise	0.6 cc. normal acid.
4. " "	0.5 cc. "

It is sufficiently proved by these results that the papers do not contain free acid; on the other hand, that they do

contain sulphate of alumina, but in the form of a *basic salt* with a ratio $\text{SO}_4 : \text{Al}_2\text{O}_3$; *certainly less than 5:2*. (Compare this Journal, 1886, 73; 1889, 253.)

We do not deny of course that papers *may* contain free acid, and it is not for us to say that the papers examined by Professor Hartley did not contain free acid. What is certain, however, and what we desire to emphasise, is that the *evidence* adduced by him being merely that of an *acid reaction*, is no proof whatever of the presence of free acid. We now suggest the only probable explanation consistent with the experience* of specialists, and with the results of examination of fair, trade samples of the particular papers which he has found to possess the serious defect in question, and Professor Hartley will no doubt take this suggestion into consideration in any further investigations on this subject.

We may now look a little more generally at the important questions opened up by the communication which we have found it necessary thus to criticise.

1st. Is the "acidity" of a sulphate of alumina more or less basic—which we take to represent a normal acidity of hard-sized papers—prejudicial to the permanence of pigments applied in the form of water colours to the paper containing this salt? The answer to this must come from those who have made a special study of pigments in relation to the conditions under which they have to struggle, so to speak, to retain their beauty unimpaired.

2ndly. Admitting for the moment that the condition of "acidity" does prejudice the life of pigments, is it in the power of the paper maker to suppress this acidity without prejudicing on the other hand the quality of his paper *quâ* paper?

To this question we can give an answer based upon experience. Most of the high-class papers made in the Kentish district are finished with a neutral or slightly basic reaction. There is every reason, *a priori*, why this should be so. The souring of bleached rags is an exceptional treatment, and, this excluded, the treatment which the rags undergo, *i.e.*, boiling and bleaching, are uniformly with alkaline or basic reagents. The alum of the size is then the only contributor of acid, and to its action is opposed, in addition to the basic residues from the above treatments, that of the exceptionally hard waters (14–20 grms. CaCO_3 per gallon) used in the manufacture—and we may reckon at the very lowest 5,000 gals. per ton of paper used on the machine—and also that of the soap, which is a usual ingredient of the mixture used in sizing.

Thus at Messrs. Joynson's mills, St. Mary Cray, where the process of souring the rags is seldom resorted to, the papers produced, including the drawing paper, finish with a neutral or slightly basic (to litmus) reaction.

At Messrs. Balston's mill, where the "Whatman" papers are made, the souring process is practised; but the condition of the subsequent treatments are so adjusted that the alum used in the sizing is reduced to the condition of a basic sulphate in the finished paper.

Our final conclusions are therefore these—

(1.) The "acidity" of drawing and other papers—when normally acid—is not due to the presence of *free acid*, but to sulphate of alumina, always more or less "basic," but with reactions which are acid to certain indicators.

(2.) That if shown to be a defect in relation to any uses for which the papers are intended, the acidity may be suppressed by the adoption of very simple expedients, without prejudice to the qualities of the papers.

DISCUSSION.

Mr. WM. THORP had not heard the original paper, and therefore was not fully informed on the subject. His experience had been that it was easier to get chemicals into fibres than to get them out. He had first encountered the question in the case of water analysis some years ago, when it had been necessary to free filter-paper from ammonia. He had passed many litres of water, free from

* The sum of the evidence adduced by Professor Hartley is the acid reaction *together with* precipitation of BaSO_4 on adding BaCl_2 to the aqueous extract. The *a priori* interpretation of this evidence should have been the presence of a sulphate having acid reactions.

ammonia, through a filter, and the ammonia was present in the filtrate to the end of the chapter. That led him to the conclusion that the ammonia was present inside the fibre of the paper, and required time for removal. The difficulty was overcome by soaking the filters for some days in water free from ammonia, then, on using them without drying, they imparted no ammonia to the filtrate. His remarks were made, not so much as a criticism of the paper, but as a hint to those present as to the difficulty of removing soluble substances from fibres.

Dr. SAMUEL RIDEAL thought that the authors' statements came rather late in the day. He was under the impression that the last numbers of the *Chemical News* and *Proceedings of the Chemical Society* contained a paper by another author, who stated that the presence of sulphuric acid was probably due to alum being present in the fibre of the paper. There was one point which had not been raised by the authors, and which was mentioned in the discussion on the original paper by Professor Hartley, namely, whether it might not have been possible that the papers had absorbed sulphuric acid from the air. That would exonerate the manufacturers, but at the same time render it possible for sulphuric acid to be present. He had been offered a sample of Whatman's paper, made in 1837, and he would be very glad to present it to the authors of the paper if it could be of any use to them.

Mr. JOSEPH ARNOLD, as a manufacturer of one of the papers mentioned, would like to state that no acid whatever had been used in the manufacture of his papers, they were simply made of linen and cotton rags washed in pure water, no acid, chlorine, or chemical of any kind being used. He could not, therefore, understand how Professor Hartley could find acid in his (Mr. Arnold's) paper.

Mr. W. F. ANDERSON, as one who had had a wide experience in making drawings, would like to say that he was always under the impression that drawing paper was made of linen, and cartridge paper of cotton. There was a very great difference between proper drawing paper and cartridge paper. He had known the size to disappear from the paper, and had in fact found that a roll of drawing paper invariably got spongy after 12 months, owing to that cause. Those who were makers of drawing paper would do well to look into that point. He did not know what the paper mentioned by Dr. Rideal made in 1837 could be. If he was right in his suspicions, it would be little better than blotting paper now.

Dr. RIDEAL thought it would be interesting to see whether the paper referred to contained any alum, *i.e.*, whether the sizing had been rendered anti-septic by the addition of alum. As the paper referred to had been exposed in a stable for 20 years, any sulphuric acid which might have been present would probably be found as ammonium sulphate.

Mr. R. GALLON explained that the reason why paper became spongy was that it was not kept properly. Paper was a most delicate substance to keep in working order, and after a few years the size would be affected by damp, and sponginess and spottiness would ensue.

Mr. BEVAN, in reply, said that with reference to Mr. Thorp's observation as to the difficulty of removing chemicals from fibre, he would like to point out that this difficulty chiefly applied to solutions of an alkaline nature. It was well known that it was extremely hard to remove caustic soda from cellulose, but it was a simple matter with acid. The process to which rags were subjected was much more drastic than any laboratory treatment. The rags were broken up until they formed almost a milk in the water. Referring to Dr. Rideal's remarks as to the possibility of the paper being acid on account of the action of sulphurous acid derived from coal-gas, if the facts were as he (Dr. Rideal) had stated, Professor Hartley ought to set the matter right, so as to exonerate the paper-maker. He (Mr. Bevan) presumed that Mr. Arnold's statement that no chemicals were used in the manufacture of his paper referred to the first treatment of the rags. He supposed

Mr. Arnold would not wish it to be understood that no chemicals were used in the sizing. (Mr. Arnold remarked that chemicals *were* used in the sizing.) He (Mr. Bevan) would point out that certain makes of paper, such as Joynson's, not only contained no free acid, but actually gave a slightly alkaline action to certain reagents.

EXPLOSIVE NITRATES FROM THE JUTE FIBRE.

BY C. F. CROSS AND E. J. BEVAN.

In a recent issue of *Dingl. Polyt. J.* **283**, 88, we read a communication by Otto Mülhäuser under the title, "Die Jute ein Rohstoff für Schiesswolle."

Following the appearance of this communication, we observe that the journal "*Industries*," 1892, 236, gives prominence to an abstract of the author's results under the title, "Nitrojute, a New Explosive."

Those who have studied the chemistry and chemical technology of the jute fibre will, with ourselves, be anxious to discover what Dr. Mülhäuser has contributed to the advance of either, or both.* The substance of the communication in question we take to be the quantitative study of some four preparations of the well-known explosive nitrates obtainable from this fibre. The conditions of "nitration" chosen were a comparatively long immersion in the nitrating acid, the composition of which (ratio $H_2SO_4:HNO_3$) was varied, as was also the proportion of acid to fibre. With the long exposure (3—4 hours) to the nitrating acid, there is, as the author states, a disintegration of the fibre bundles, and the nitration is attended by secondary decomposition and conversion into products soluble in the acid mixtures. These facts were fully described by ourselves some few years ago (*Chem. Soc. J.* **55**, 202), and from them we concluded that the highest yield of nitrate is represented by an increase of weight of 55 per cent., corresponding approximately with the formation of a tetranitrate of the *ligno-cellulose*, which latter we formulate for statistical purposes as $C_{12}H_{13}O_9$. In this product the general structural features of the original fibres are preserved. This high yield is only obtained with exposures of short duration: in fact, after 15 minutes' immersion at the ordinary temperature, decomposition is usually seen to ensue with liberation of gas and the appearance of nitrous fumes.

In Mülhäuser's experiments it is evident, from the conditions of the treatment and from the low yield of the products (130 per cent.), and from the disintegration of the fibre bundles, that such secondary decompositions took place, and that the products probably, therefore, approximate to derivatives of *cellulose* rather than of the *ligno-cellulose*, the more oxidisable "non-cellulose" or lignone constituents having suffered decomposition.

The author, in fact, regards his product as a *cellulose* pentanitrate— $C_{12}H_{13}O_5(ONO_2)_5$, but appears to consider it unnecessary to account for the intermediate steps by which such a product has been obtained from a compound cellulose (of the approximate formula $n.C_{12}H_{13}O_9$). We have suggested the above explanation on the basis of our own researches, and hope that it may receive due consideration in any further investigations which the author may carry out on the subject.

From the point of view of technological application, we have always failed to see any advantage in the lignified textile fibres as raw materials for explosive nitrates.

There are a large number of raw materials approximating more or less to a pure cellulose which can be obtained at from 10*l.* to 25*l.* a ton, and which will yield on treatment from 150 to 170 per cent. of explosive nitrate, superior in explosive power and stability to the products obtainable from jute *et similia*. In our opinion, therefore, the application of the latter is not within the range of practical consideration.

* Dr. Mülhäuser's views of the constitution of the jute fibre as a chemical individual are hardly reconcilable with our own (*Chem. Soc. J.* 1889, 666; 1882, 90; 1889, 199; *Chem. News*, 77)

On the other hand, there are certain raw fibrous materials which yield nitrates of very distinctive characteristics, *e.g.*, the Sunn hemp (*Crotalaria Juncea*) and the Madar fibre* (bast fibre of *Calotropis gigantea*). These certainly invite investigation, both from the scientific and practical point of view, and we hope that Dr. Müllhäuser will extend his investigations to include these and other raw materials, as also to clear up some of the points which he has left untouched in his study of the "nitration" of the jute fibre.

BETTING'S BALANCE.

EXHIBITED BY MESSRS. GROSSCURTH AND LUBOLDT.

This balance aims at two ends. One, securing greater accuracy by reason of non-exposure of the working parts during the operations of weighing. The second, preserving the weights from the inevitable wear and tear which constant handling entails, and also to facilitate the speed at which weighing can be performed.

The beam is stiffened in an upward direction, and the possibility of its bending reduced to a minimum. The planes are all of agate.

The weights are made to rest, when not upon the pan, on forked levers worked from the outside. The same method is employed for the riders, so that the minimum of exposure and the maximum of convenience are gained. A provisional specification has been filed.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held Friday, February 5th, 1892.

MR. IVAN LEVINSTEIN IN THE CHAIR.

A DISCUSSION took place on the New Building Bye-Laws, 1890—1891, issued by the Manchester Corporation, in the course of which it was pointed out that annoyance and injury would be inflicted on those engaged in the chemical and allied trades if they were compelled to submit plans of apparatus and plant before erecting them. It was also contended that the word "building," as used in the bye-laws, was intended to refer only to public buildings, warehouses, shops, and residences, and not to chemical works

or the plant therein; and a desire was expressed to obtain an authoritative definition of the term "building" from the Corporation.

Finally the following resolutions were passed:—

1. "That, in the opinion of this meeting of the Manchester Section of the Society of Chemical Industry, annoyance will be caused and injury inflicted on all persons engaged in the chemical and allied industries if the bye-laws of the Manchester Corporation, 1890 and 1891, referring to new streets and buildings be interpreted by the Corporation as also applicable to plant."

2. "That the Chemical Section of the Manchester Chamber of Commerce be requested to consider the Bye-Laws of the Manchester Corporation of 1890—1891, referring to new streets and buildings, so far as the same affect the interests of those engaged in the chemical and allied industries."

ERRATA.

This Journal, 1892 (February Number), page 131, col. 1, 19 lines from bottom of page, after the word "moisture," insert the following:—"makes it appear probable that the action is one of oxidation. The following word "That," to begin a fresh sentence, as "That modification," &c.

This Journal, 1892 (January Number), page 8, col. 1, the last line should read:—

" „ „ unfiltered, &c."

THE ESTIMATION OF SILICA IN CLAY.

BY L. ARCHBUTT, F.R.C., F.C.S.

DURING the last few years, at least two writers have called attention to errors inherent in the usual process for determining silica in silicates, errors which have not recently been discovered, but against which we have long been warned, but perhaps not sufficiently, by Fresenius at any rate.

George Craig (Chem. News, 60, 227) states that by fusing pure silica or siliceous matter with mixed alkaline carbonates, decomposing with HCl, and evaporating to dryness, not more than 97.5 per cent. of the silica can be found in the insoluble residue left on dissolving up, and this statement has led James P. Gilbert to make a number of experiments with silicates of different compositions, the results of which are given in a valuable paper to be found in the Chem. News, 61, 270 and 281.

Gilbert's experiments show that in the analysis of silicates containing Al_2O_3 , but which are practically free from CaO and MgO, dehydration, even at the high temperature of $280^\circ C$, will not prevent some milligrammes of the silica

* See Report on Indian Fibres by Cross, Bevan, and King, E. and F. N. Spon, 1887.

from passing into the filtrate, so that in accurate analysis the silica in the filtrate must *always* be recovered; and, secondly, that it is better to dehydrate at a temperature of 100° C., because the silica obtained is purer by dehydrating at that temperature than at higher temperatures, and quite as much is rendered insoluble.

As the presence of TiO_2 in clay makes it always necessary to volatilise the silica with HF after weighing it, the presence of a little more impurity is of no great consequence; and as silica cannot be prevented from passing into the filtrate, it seems best to estimate silica on a separate quantity of clay, and to estimate the other chief constituents in a portion of the clay from which all silica has been removed by treatment with HF and H_2SO_4 .

It has been pointed out by L. Smith (Fres. Quant. Anal., 7th edition, 1, 192) that the silica obtained by decomposing clay by means of KHSO_4 is liable to contain a large amount of impurity owing to the formation of a sparingly soluble double sulphate of Al and K, but 1 was not prepared to find that the silica obtained by this method is liable to be considerably below the truth.

The clays which were subjected to analysis contained SiO_2 from 46 to 53 per cent., Al_2O_3 from 21 to 24 per cent., Fe_2O_3 from 7 to 13 per cent., alkalis from 2 to 3½ per cent., H_2O (combined and moisture) from 8 to 10 per cent., with smaller quantities of TiO_2 , FeO , CaO , and MgO . 1 gm. of the clay, rubbed as fine as possible in an agate mortar, was fused for 2 hours with 10 grms. of pure KHSO_4 which had previously been fused till quite calm. The temperature during the whole time of the fusion was not higher than that required to maintain the contents of the covered platinum crucible quite fluid. The melt was then placed in cold water mixed with some H_2SO_4 , and left to dissolve. The insoluble residue was washed until the washings gave no precipitate with BaCl_2 even on standing, and the dried siliceous matter was ignited at the highest temperature of the muffle until constant in weight. The SiO_2 was then volatilised with HF and H_2SO_4 , and the residue was again ignited until constant in weight. The results obtained were as follows:—

No. of Sample.	Time fused.	Pure SiO_2	Residue left by HF calculated as per Cent. of original Clay.
		Per Cent.	
1	1 hour	50·65	4·0
1	2 hours	50·51	4·3
2	"	51·70	3·0
3	"	45·65	3·35
4	"	49·25	3·55
5	"	49·25	13·00
6	"	50·75	4·5

Wishing to obtain a confirmation of these results, I determined the SiO_2 in the first three samples by the mixed carbonates method carried out as follows:—1 gm. of the finely-powdered clay was fused with 5 grms. of pure mixed carbonates and a little KClO_3 . The fusion was extracted with water, decomposed with excess of HCl , and dried up over a steam-bath, the solution being stirred well just at the last to reduce the residue to small grains. The dish was covered with a clock glass and placed in the air oven at 150° C. for one hour. It was then allowed to cool, the residue was treated with 10 cc. of HCl (1·11 sp. gr.) and 20 to 30 cc. of water, and heated on the steam-bath for a short time in the covered dish, then dried down and again heated to 150° C. for one hour. The dry residue was now digested with 20 cc. HCl in the covered dish for half an hour at a gentle heat, then water was added, and the dish was heated on the steam-bath. Finally, the silica was filtered off, washed, dried, and weighed, after ignition at a high temperature till constant. The SiO_2 was then volatilised as SiF_4 and the residue was weighed.

The following results were obtained:—

No. of Sample.	Pure SiO_2	Residue left by HF and H_2SO_4 calculated as per Cent. of the Original Clay.
	Per Cent.	
1	51·15	0·45
2	51·75	0·45
3	45·65	0·95

It will be seen that No. 2 clay gave the same result by this method as by the KHSO_4 method; but Nos. 1 and 3 gave results from 0·5 to 0·7 per cent. higher. At this stage the work had to be set aside for several weeks, and, on resuming, it was thought desirable to try the effect of decomposing the clays by fusion with mixed carbonates and then evaporating with sulphuric acid.

It was decided, however, not to decompose the solution of the fusion at once with H_2SO_4 and evaporate, because, according to Gilbert, this leads to obtaining silica which is very bulky and gelatinous. The solution was therefore first evaporated to dryness with HCl , and then in the case of No. 1 clay 20 cc. of pure concentrated H_2SO_4 were added, and when the violent effervescence had ceased the lid was removed from the dish and the evaporation was carried on until H_2SO_4 fumes were evolved. The residual contents of the dish were cooled, treated with 20 cc. HCl (1·1) and some water, and digested hot for one hour, then filtered.

It was observed that the SiO_2 contained small lumps, which were not altered by heating with HCl . In the case of No. 2 clay, 25 cc. of sulphuric acid were added to the dry HCl residue, and when action had ceased, the rod and sides of the dish were rinsed down with water and the solution evaporated until H_2SO_4 fumes came off. In the case of No. 3 clay, the residue left by evaporation with HCl was first treated with enough water to dissolve up the KCl and NaCl , and then 20 cc. of pure sulphuric acid were added, by degrees, to avoid loss by the violent effervescence which occurred, and then evaporated till H_2SO_4 fumes came off.

The SiO_2 obtained in each of these experiments was lumpy. After filtering and washing, the filtrates were evaporated and again heated until H_2SO_4 fumes came off strongly. On dissolving up in HCl and water it was found in each case that a further small quantity of silica had been rendered insoluble. This further quantity was weighed separately in the case of No. 1, but in Nos. 2 and 3 it was added to the main quantity.

The following results were obtained:—

No.	Main SiO_2	SiO_2 out of Filtrate.	Total Pure SiO_2	Residue left by HF and H_2SO_4 calculated as per Cent. of Original Clay.	
				Out of Main Silica.	Out of Second Silica.
	Per Cent.	Per Cent.	Per Cent.		
1	50·52	0·89	51·32	1·4	0·05
2	52·73	0·84	
3	46·36	0·99	

It will be seen that these results are from 0·17 to 0·98 per cent. higher than the last, although dehydration had been effected by heating with H_2SO_4 . It seemed to me, therefore, that the reason why the KHSO_4 method first used had given low results might be due to the fact that the clays had not been ignited before fusion, and that the water which they contained had never been completely expelled at the temperature of the fusion.

To test this, 1 gm. of No. 1 clay was taken first heated to strong redness for 10 minutes, and then fused with KHSO_4 for 2½ hours at as high a temperature as could be obtained without driving off much H_2SO_4 . The fusion when cold was heated

with HCl (1·1) and water in about equal volumes, instead of treating with cold dilute H₂SO₄. This was done to try and obtain a purer silica. After filtering and washing the filtrate was evaporated with 20 cc. of pure concentrated H₂SO₄ and heated until fumes came off strongly for some time. This resulted in the obtaining of a little more silica, which was filtered off. The filtrate was evaporated a second time until H₂SO₄ fumes came off strongly, and again dissolved up. This time a mere trace of insoluble matter remained. It was, however, filtered off and the two recovered traces were weighed separately. The result obtained was:—

	Per Cent.	Per Cent.
Pure SiO ₂ (main quantity)...	50·96 plus a residue of	4·09
Pure SiO ₂ (from filtrates) ...	0·45 plus a residue of	0·05
Total pure SiO ₂	51·41	

It seems from these experiments almost hopeless to obtain by a single dehydration the whole of the silica, and I have therefore provisionally adopted the following method as being upon the whole the least troublesome and the most reliable.

The Process.

1. Strong ignition of 1 gm. of the finely powdered clay.
2. Fusion with 5 grms. of pure mixed carbonates.
3. Extraction with water (about 200 cc.), acidifying with HCl in good excess, and evaporating to dryness on the steam-bath in a porcelain dish, reducing the residue to small grains.
4. Heating the dish and dry residue in an air oven to 150° C. for 1 hour.
5. Dissolving up in HCl and water, filtering, and washing the silica.
6. Evaporating the filtrate with 20 cc. of strong H₂SO₄, till fumes are evolved *very strongly*. The acid will fume before it is fully concentrated, and the object to be aimed at is to heat till the acid is fully concentrated.
7. Dissolving up in HCl and water, filtering, and washing the additional small quantity of silica.
8. Igniting the mixed silicas at the highest temperature of the muffle until constant in weight. Then volatilising with HF and a few drops of H₂SO₄, and igniting the residue till constant in weight. The difference is pure SiO₂. The last three out of the six clays were treated in this way, but the recovered SiO₂ was weighed separately for information.

No.	Pure SiO ₂ (per Cent.)			Residue left by HF, calculated as per Cent. of original clay.	
	1st ppt.	2nd ppt.	Total.	1st ppt.	2nd ppt.
4	50·72	0·70	51·42	0·15	0·05
5	51·32	0·90	52·22	0·15	0·05
6	51·93	0·40	52·33	0·24	0·05

For easy comparison I have arranged the results in the following table:—

PERCENTAGE OF PURE SiO₂ OBTAINED.

No.	By fusion of unignited Clay with KHSO ₄ for 2 hrs. at temperature just high enough to keep the mass quite fluid.	By fusion of ignited Clay with KHSO ₄ for 2½ hrs. at higher temperature, and evaporating filtrate with H ₂ SO ₄ .	By fusion with mixed Carbonates and dehydration twice at 150° C. in the usual way.	By fusion with mixed Carbonates, dehydration once at 150° C., and heating filtrate with H ₂ SO ₄ .
1	50·65	51·11	51·15	51·32
2	51·70	..	51·75	52·73
3	44·95	..	45·65	46·36
4	49·25	51·42
5	40·25	52·22
6	50·75	52·33

It is evident from these results that sulphuric acid cannot be depended upon as a dehydrating agent for silica unless the evaporation be pushed to the extreme.

DISCUSSION.

Dr. CLOWES asked if any check experiments had been made with pure silica, and wished to know if the highest results obtained really represented the total amount of silica present in the clay?

Mr. WHITELEY asked if any other dehydrating agents had been tried besides pure sulphuric acid?

Mr. ARCHBUTT replied in the negative, and said that the results did not pretend to be any more than one of those incomplete investigations which not unfrequently had to be undertaken in the ordinary routine of laboratory work.

SESSION 1891—92.

1892:—

April 4th.—Annual Meeting.

Mr. Thomas Fairley. "On the Analysis of Coal-Gas for Impurities."

Mr. H. R. Procter. "On the Analysis of Gaubier." (II.)

Meeting held Monday, March 7th, 1892.

SIR JAMES KITSON, BART., IN THE CHAIR.

MEASURES.

BY SYDNEY LUPTON, M.A.

At first sight nothing seems more easy than for a Government to provide a uniform and accurate system of measures, and to render the use of it compulsory throughout its dominions. When we examine a little further into the matter, we cease to be surprised that all the labour and ability which has for so long been expended upon the subject has produced such very unsatisfactory results.

Our system of measures has gradually grown up by a series of survivals of what was considered to be the fittest, and ought in reality to be treated from an historical point of view. Want of time, and the fact that I am addressing those specially interested in the use of units as they now are, compels me to omit all historical and theoretical details, and many different kinds of measures such as those of value, time, and angles, and to confine my remarks to the more common measures of length, area, volume, mass or weight, density or specific gravity.

Two systems of measures only are so widely used as to require special discussion, the English or imperial system, and the metric or French system.

Speaking very roughly, the imperial measures may be said to be used more or less in Great Britain and Ireland, the British possessions, the United States, and to a small extent in Russia. In all these countries the metric system is permissive. The metric system is used throughout the continent of Europe, except in Russia and Turkey; in Central and Southern America, and in Japan. In all these countries survivals of older systems are used along with the metric. Outside these limits each country uses a special system of measures of its own.

Before we can usefully discuss the two systems, it is necessary to dwell in some detail upon three conditions which are universally present and affect all systems of measurement. They are (i.) temperature; (ii.) the pressure of the air; (iii.) gravitation, or the attraction of the earth.

(i.) Speaking generally, substances expand when they are heated, and therefore some definite temperature must be chosen at which our measures are to be made or to which they must be reduced by calculation.

In the English system 62° F., $16^{\circ}6$ C., or one-sixth of the distance between the freezing and the boiling point of water, has been selected. Considerable care and accurate thermometers are required to keep a body at this temperature for any length of time; on the other hand, it is so near the ordinary temperature of our rooms, that for rough purposes any correction may be neglected.

The standard temperature in the metric system is 0° C. or 32° F.; it is easily and correctly obtained for any length of time by the use of melting ice, but is so far from the temperature at which we live that considerable corrections must in most cases be made.

—	Δ	Coeff. Lin. Exp. for 1° C.	Exp. 0° to $16^{\circ}6$ C.
Brass	8.1	0.000019	0.00031
Bronze (Baily's metal)	8.4	0.00001774	0.0003
Iron	7.8	0.0000112	0.00019
Platinum	21.5	0.0000086	0.00014
Glass	2.5	0.000009	0.00015
Pine wood	0.56	0.000005	0.00008

—	Δ	Coeff. Cub. Exp. for 1° C.	Exp. 0° to $16^{\circ}6$ C.
Water	10	From 4° C.	0.00112
Mercury	136	0.00018	0.003
Platinum	215	0.0000257	0.00013
Air	0.0013	0.00367	0.061

(ii.) The second condition affects only the apparent mass of bodies. We live and work in an atmospheric ocean which exercises a pressure varying about a pound each way from a mean value of 14.7 lb. per square inch (1,033.3 grm. per sq. cm.) on every surface exposed to it. Solids and liquids are practically unaffected by this change of pressure, but the mass of a given volume of gas, such as the air itself, varies directly with the pressure upon it. The pressure of the air is measured by the barometer, that is, by the height of the column of mercury which balances it.

On the English system the standard height of the barometer is 30 in. at 62° F.; on the metric system, 760 mm. at 0° C. Hence the English standard is equal to $30 \times 25.4 = 762$ mm. of the metric standard.

When two bodies are counterpoised in a balance, each apparently loses a weight equal to the weight of the air which it displaces. So that the true weight of a body is its

apparent weight + the weight of the air which it displaces — the weight of the air displaced by the weights—

$$W = w + w \left(\frac{1}{\Delta_s} - \frac{1}{\Delta_w} \right) (a)$$

The weight (a) of a cubic centimetre of air at the temperature t° C. under a barometric pressure h mm. when the tension of aqueous vapour is v mm. and the attraction due to gravitation is g , is—

$$(a) = \frac{0.001293}{1 + 0.00367 t} \times \frac{H - 3 v/8}{760} \times g/g_{45}$$

The correction is usually a small one, amounting to the addition of 1.06 grm. when a litre of water is weighed against bronze (Δ 8.4) weights.

(iii.) The last condition introduces a small correction when masses are compared by a spring-balance at different places, or work is measured in units, such as foot-pounds or kilogramme-metres, which depend upon the attraction of the earth.

The attraction which the earth exercises upon a body is measured by twice the distance through which the body would fall freely towards it from rest in a second. This distance is usually measured in feet or metres, and symbolised by g . By comparing pendulum observations taken as far as possible all over the world, it has been found that g varies with the latitude. Each nation used to take the value of g in its own capital as the standard attraction of the earth, but the value of g at sea-level in latitude 45° has now been generally accepted as the unit. The value of g at any other place in latitude ϕ may be calculated from $g = g_{45} (1 - 0.00257 \cos 2\phi)$. If the place of observation be situated on a flat plain h metres above sea-level, g is further decreased by a coefficient $(1 - 0.0000002 h)$. The following table gives a few of the more important values of g at sea-level:—

$$g = g_{45} (1 - 0.00257 \cos 2\phi)$$

$$g_{45} = 32.1727 \text{ ft.} = 9.80606 \text{ metres.}$$

Approximate Place.	ϕ	g .
Equator	0°	0.99743
Bordeaux.....	45°	1.0000000
Paris O.	$48^{\circ} 50' 11''$	1.0003432

A pound weight true at Bordeaux would apparently weigh nearly $5\frac{1}{2}$ grains too much on a spring-balance in Leeds, and the work done in lifting a pound through a foot in Leeds is about 1.0008 of that done in performing the same operation in Bordeaux.

In each of the systems there are two fundamental units, that of length and that of mass:—

The yard is the distance between two fine lines cut on plugs of gold sunk in a bar of Baily's metal.

The pound is the mass of a cylinder of platinum marked P.S. This cylinder has the specific gravity 21.1572 com-

pared to water at 62° F. and displaces 0.40282 grains of standard air.

The metre is the length of a rectangular platinum bar known as the Metre des Archives.

The kilogramme is the mass of a cylinder of platinum known as the Kilogramme des Archives. ($\Delta 20.5487?$)

Both these metric standards are not very satisfactory, the platinum is of low and uncertain density and probably impure. The shape of the metre is not theoretically the best and it has been accidentally injured.

Numerous copies of these standards have been made to save the wear and tear of frequent reference to them.

Thus the brass commercial standard pound (W) ($\Delta 8.143$) has the same weight in vacuo as P.S. displaces 1.04706 grains of standard air and is assumed as the unit for all ordinary weights.

The brass commercial standard kilo. ($\Delta 8.206$) is used for a similar purpose in France.

From these fundamental units all the other subsidiary units are obtained; thus the acre is 4,840 square yards, and the hectare is 10,000 square metres.

The measures of volume would seem to follow naturally from the cubes of the measures of length, but in practice they are obtained from the measures of mass.

The gallon is the volume occupied by 10 lb. of water weighed in air against brass ($\Delta 8.143$) weights, understand at sea-level in London. It is nearly 0.16 of a cubic foot.

The litre is the volume occupied by a kilo. of water at 4° C. in vacuo; for all practical purposes it is a cubic decimetre. This close connexion between the measures of volume and length is a marked advantage in the metric system.

The so-called Mohr's litre, somewhat largely used by German men of science, is the volume occupied by a kilogramme of water weighed in air at 17.5° C. and 760 mm. against brass weights; it is about 1.00231 of a true litre.

The density of a substance is measured by the number of units of mass contained in the unit of volume of it.

The specific gravity of a substance is measured by the number of times it is heavier than an equal volume of some standard substance, usually water.

Owing to the relation between the kilo. and the cubic decimetre of water in the metric system, specific gravity referred to water at 4° C. and density measured in kilo. per cubic decimetre or grammes per cubic centimetre are expressed by the same number.

In the English system, specific gravity must be multiplied by 62.2786 (mass of a cubic foot of water) to obtain density in commercial pounds per cubic foot.

For technical purposes use is made of many hydrometer scales which give specific gravities referred not to water but to some other liquid too often entirely hypothetical. Three common examples may be mentioned.

Sykes' hydrometer, used in the English Excise, sinks to zero in "standard alcohol" which has a specific gravity of 0.825 at 60° F. The scale is marked with 11 divisions, and weights numbered from 10 to 90 can be added below the surface of the liquid. A table supplied with the instrument gives the proportion of "proof spirit" specific gravity 0.919 at 60° F.

The scale reading of Twaddell's hydrometer multiplied by 5 added to 1,000 gives the specific gravity referred to water taken as 1,000.

In Beaumé's scale for liquids heavier than water, the zero point is the density of water, while the specific gravity of a solution of 15 parts of salt in 85 parts of water is marked 15 ($\Delta 1.1116$), equal divisions are continued to 68 at the base of the rod ($\Delta 1.8425$).

In the metric system all multiples and sub-multiples of the unit are obtained by the use of 10 and its powers. The convenience of this method for working at sight or for using tables is enormous, but the multiplier is occasionally too large or too small for convenience, i.e., the foot is much more useful than the decimetre.

The English multipliers seem to have been chosen haphazard and the result is not satisfactory. A mile contains 1,760 yards and a yard 36 inches, it does not occur to every-one automatically that a mile contains 63,360 inches.

The relative advantages of each system may be briefly summed up as follows:—

Of the metric system:—

- (i.) Decimal multiplication and division.
- (ii.) Close connexion between measures of length, area, volume, mass, and density.
- (iii.) Standard temperature easily obtained.

Of the English system:—

- (i.) The foot and pound are found practically to be more convenient units than the decimetre and kilogramme.
- (ii.) The standard temperature is nearly the mean ordinary temperature, hence the reductions are small and may frequently be neglected.
- (iii.) Multiplication and sub-multiplication by 12 or 2 is often more convenient than that by 10.

One of the strongest and most effective arguments for the introduction of the metric system into France was the intolerable burden of the great variety of measures which it superseded. The same argument has not lost its force in England at the present time. Almost every petty town and every trade has its own special measures for the bewilderment of the learner and the confusion of the trader.

Many local measures seem luckily to be dying out, and there seems some hope that the 16 different acres which were in use in Great Britain and Ireland a few years ago may shortly be reduced to one. On the other hand, each trade seems to demand its own peculiar measures; thus, an imperial stone is 14 lb., a stone of glass 5 lb., a stone of meat 8 lb. in London, 10 lb. in Leeds, a stone of sugar or butter 16 lb., and a stone of hemp 32 lb.

Owing to the complication of our systems of measures but few children in our elementary schools progress in arithmetic beyond the tedious subjects of measures and money, and a very easy calculation shows that at least 500,000,000 working hours are annually wasted in elementary schools.

Trade customs also afford to the dishonest trader great assistance in fraud; a purchaser would expect a blanket 12 quarters wide to measure 9 feet; he finds by the custom of the trade it measures only 7 feet. A quarter being not 9 inches but 7. A further iniquity is the introduction into trade of "reputed" pounds or stones, which simply means that the purchaser buys paper at the price he is willing to give for tea or tobacco. In any individual retail transaction this seems a very small amount, but the true measure is the weight of paper used by the retail trader in a year. Each ton he has bought at 3d. a pound and sold as tea at 2s., has put 196l. of illicit gain into his pocket.

Everyone will probably admit that such trade measures and customs as the above ought to be absolutely and entirely abolished.

Three ways out of the difficulties of our present system seem to be possible, though each way bristles with difficulties:—

- (i) to adopt an entirely new system.
- (ii) to adopt the metric system with possibly some small alterations which would probably be accepted by those nations which now use it.
- (iii.) to keep as nearly as possible our present units, but to modify the sub-multiples and multiples, and to make the connexion with the metric system easy.

(i.) No one has yet been bold enough to propose an entirely new system of measures for general adoption. The C.G.S. system, which expresses all measures in terms of the centimetre, gramme, and mean solar second, has met with very limited acceptance, even among men of science, and in practice the Board of Trade unit, the 1,000 watt-hours, or 3,600,000 volt-coulombs, has invaded the very electrical sanctuary of the method.

For engineering purposes Rankine proposed the general use of the foot, pound, and second.

Both these systems, though good in theory, require the use of very small and very large numbers. We are more accustomed to think and speak of a week than of 604,800 seconds.

(ii.) Most men of science, who are habituated to the facilities of the metric system, desire at once to make it, with all its faults, universally compulsory.

I may quote for their consideration from Mr. Christolm's report to the Royal Commission in 1869, five slightly modified objections to the metric system, and add three others:—

- (a.) The metre and the kilogramme are not the scientific units which they profess to be, but only a definite length and a definite mass.
- (b.) The relation between the kilogramme and the cubic decimetre of water is *not* exact.
- (c.) The original metric standards are very imperfect in construction, and to a certain extent impaired by use. They are the absolute property of the French Government.
- (d.) Though the decimal division has great advantages, there are some counterbalancing disadvantages. Thus, while 10 is exactly divisible only by 5 and 2; 12 may be divided by 6, 4, 3, 2. And again, to weigh from 1 to 10 decimal subdivisions, five weights—1, 1, 1, 2, and 5—are required, while with binary subdivisions, five weights—1, 1, 2, 4, 8—will weigh from 1 to 16. Duo-decimal or binary division seem in some respects more adapted to the practical needs of the people, *e.g.*, mechanical engineers use the binary subdivisions of the inch.
- (e.) More than 30,000,000 of our present measures would have to be thrown aside as useless, and the cost of replacing them would be considerable. A large number of bottles, casks, &c. would have to be re-made.
- (f.) Though the metric system has been permissive in England since 1864, and in India since 1870, it has not come at all into practical use, which seems to show that the need is not equivalent to the trouble and cost of the change.
- (g.) The metric system has no units so practically convenient as the foot and the pound.
- (h.) The metric names are so cumbersome and pedantic that they must be changed before the system is introduced into England.

I believe that the opinion of men of business, on the other hand, is almost unanimously opposed to the introduction of the metric system.

Some may at once ascribe this opposition to the natural conservatism and obstinacy of the British mind, especially where trade customs are concerned. I prefer to attempt to investigate the causes which give rise to the feeling.

So far as measures are concerned, the operations of trade may be classed as manufacturing, internal, and external.

(a.) In the great majority of manufacturing operations proportions arrived at by trial and continually used are quite familiar to the workmen. In comparatively few cases does the master or scientific adviser arrive at theoretical results by the aid of the metric system and translate them for the use of the workman.

(b.) In the case of internal trade the manufacturer, wholesale dealer, and retailer soon becomes familiar with the comparatively few measures used in his own special branch, and gets over any difficulties of calculation by traditional rule of thumb or the use of tables. Unfortunately, as has already been pointed out, so far as the general public go, the legal maxim "*caveat emptor*" is only too true, and opportunities for fraud should be minimised by the abolition of trade customs. Were this reform strictly carried out, in retail trade at all events, experience in France does not seem to show the great superiority of the metric system.

(c.) External trade. Many of our Consuls abroad declare that we lose a good deal of export trade owing to supplying our goods of a length and weight not generally understood, and that we should sell more if the goods were packed according to the metric system. How far there is real ground for this suggestion is a matter for the careful consideration of traders; but an outsider would imagine that if the necessity existed each firm could for itself make the few changes required without waiting for the initiation of the Government. The mere conversion of English to metric measures is very easily accomplished by the aid of a table of multiples which can almost be printed on a visiting-card.

The total value of British imports and exports in 1890 is returned as 718,000,000*l.*; of which 340 millions were transacted with countries using British measures; 300 millions with countries using metric measures; and 108 millions with countries using special measures.

It does not seem that under any of these three heads there is great urgency for an immediate change.

(iii.) In conclusion it may be expected that I should attempt the impossible, and mention modifications which might render our present system more satisfactory.

The objects to be aimed at seem to be (a.) absolute uniformity throughout the Empire; (b.) decimalisation; (c.) convenient relationships between the different kinds of measures; (d.) easy conversion to and from the metric system.

Many proposals have been made, but none fulfils all, or even the greater part of these conditions. The first very slight reform, uniformity of measures throughout even Great Britain and Ireland, would probably be stoutly resisted by traders. We should no longer have the gallon divided into four quarts, but into also six wine bottles holding 11,666 $\frac{2}{3}$ grains of water each. The gallon of beer, 33/40 of the imperial gallon, divided into eight reputed pints, and so on.

If we assume that the foot and the pound are the most convenient fundamental units, to bring them into conformity with the metric system, each must be somewhat increased, and we have:—

MEASURES OF MASS.

1 New Pound = 1.10231 Old Pound = $\frac{1}{2}$ kilo.

	Value of New Weighs in		Of Old Weights in Old Pounds.
	New Pounds.	Old Pounds.	
Grain	0.0001	0.00011	0.000113
Dram	0.01	0.011	0.0039
Ounce	0.1	0.11	0.0625
Pound	1.0	1.1	1.0
Stone	10.0	11.0	14.0
Cwt.	100.0	110.2	112.0
Ton	2,000.0	2,204.6	2,240.0

The ton would be equal to the metric tonne, and the pound to half a kilo. Many of the existing weights could be utilised by slightly reducing them.

The changes required in the measures of the length are somewhat more considerable. According to Kupffer, the metre must be reduced by four parts in a million, that a kilogramme of water at 4° C. may occupy a cubic decimetre. Suppose this change universally accepted, and the foot taken as one-third of the metre.

MEASURES OF LENGTH.

1 New Foot = 1.09363 Old Foot = $\frac{1}{3}$ metre.

1 New Foot Square = 1.196 Old Foot Square.

1 New Foot Cube = 1.308 Old Foot Cube.

	Value of New Measures in		Old Measures in
	New Feet.	Old Feet.	Old Feet.
Yot	0.01	0.0109	$\frac{1}{3}$ " = 0.104
Inch	0.1	0.1093	0.083
Foot	1.0	1.09	1.0
Yard (metre)	3.0	3.28	3.0
Fathom	10.0	10.9	6.0
Chain	100.0	109.4	60.0
Furlong	1,000.0	1,093.6	690.0
Mile	10,000.0	10,936.3	5,280.0
League	100,000.0	109,363.0	15,840.0

Three feet would be a metre, and three furlongs a kilometre, the new mile would be rather more than twice the old one. The old inch, so widely known for engineering purposes, would be very nearly represented by eight jots.

The length of 3° or 180' of mean latitude on the surface of the earth is $180 \times 6,076 = 1,093,680$ old feet, or almost exactly 100 new miles. Hence if we return to the old definition of the knot as 1' of mean latitude, we have the simple relation 9 knots = 5 miles.

The old acre of four rods contained 10 square chains of 66 feet or 43,560 square feet. Though the change is considerable it seems best to derive the measures of surface directly from the squares of the measures of length.

MEASURES OF AREA.

	Value of New Measures in		Of Old Measures in
	New Square Feet.	Old Square Feet.	Old Square Feet.
Pole	100	119'6	272'25
Rood	100 00	11960'0	10890'0
Acre	1000 000	1196000'0	43560'0

The new acre would be equal to about 27'45 old acres and the new rood to 14'51 of an old acre.

The Fahrenheit should be replaced by the Centigrade scale of temperature, and efforts should be made to abolish the last traces of Réaumur. The standard temperature for scientific and accurate work should still be the melting point of ice, 0° C. As a subsidiary standard temperature for all ordinary purposes, 17° C. or 290° absolute would be a great convenience. Thermometers accurate at that temperature to 1° are now obtainable at a comparatively cheap rate, and there does not seem to be the same necessity which there used possibly to be for reducing say all barometric readings for meteorological purposes to 0° C. For all trade purposes, specific gravities referred to water at 17° C. are sufficiently near if taken in the laboratory without reduction.

The standard height of the barometer should be still taken about as 760 mm., but at 17° C. instead of at 0° C. This would be equal to 22'8 inches at 17° C., a small reduction of about 3 parts in 1,000 would have to be made in the normal masses of gases, and the coefficient of expansion would become 0'00345.

A cubic foot of water at 4° C. would weigh $2000/27 = 74'074$ lb.; but since a cubic foot of water at 4° C. becomes 1'001162 cubic feet at 17° C. and $\frac{2}{3}$ of a cubic foot of air at 17° C. weighs about 0'08 lb., a cubic foot of water would weigh at 17° C. in air against brass weights very nearly 74 lb. Hence specific gravities referred to water at 17° C. multiplied by 74 would give densities in commercial pounds per cubic foot.

Since a kilo. of water weighed in air at 17° C. occupies 1'002223 cubic decimetres, a true cubic decimetre under the same conditions weighs 997'78 grms.

The gallon or volume of 10 lb. of water in air against brass weights would contain 135'3 new or 305'4 old cubic inches, and might be divided into five bottles or quarts and 10 pints. If a similar definition were accepted in the metric system a quart would be a litre. The use of these measures should be restricted to *liquids*; coals, grain, fruit, and other solids in small pieces should be sold only by weight.

The following numbers show the relations of the new to the old measures:—

Old wine bottle $\frac{1}{4}$ gallon = 46'2 cubic inches.

Old quart.....	63'4	New quart...	61'1	Reputed quart.	57'2
Old pint	31'7	New pint	30'5	Reputed pint ..	28'6

The pharmaceutical fluid ounce contains 437'5 grains of water, the new fluid ounce would contain 770 grains. It would possibly, however, be better to follow the German example and make up prescriptions by weight. A scruple of 10 grains, rather less than half the old scruple, might possibly be convenient.

Specific gravity referred to water at 17° C. would be expressed by the same number as stones per gallon or pounds per pint.

According to the old measures at 0° C., a cubic foot of air weighed 0'080728 lb., and of hydrogen 0'005592 lb. To convert to the new measures at 17° C.—

$$\times \frac{(1'09363)^3}{1'06239 \times 1'1023} = \times 1'117$$

hence a cubic foot of air weighs 0'09016 lb., and of hydrogen 0'006246 lb.

For all practical purposes 100 cubic feet of air weigh 9 lb., and specific gravities referred to air at 17° C. multiplied by 9 give densities in lb. per 100 cubic feet.

DISCUSSION.

The CHAIRMAN opened the discussion by remarking that he found no difficulty in our present system in ordinary commercial transactions, but in dealing with countries using the metrical system great confusion arose. In a recent visit to America he found a 2,000 lb. ton was in use throughout the iron trade. He considered that there was no possibility of displacing the inch as the mechanical unit of length, the inch being used in India and the Colonies, United States of America, Mexico, South America, &c. At the same time, in fulfilling some French and Spanish contracts his mechanics had had occasion to use the metrical system, and he found that the English mechanic readily comprehends and works the system and finds it very convenient. He considered the adoption of the metrical system would greatly facilitate the comparison of prices, &c., but would have no great advantage in ordinary commercial transactions. He would strongly advocate two simple reforms, viz.:—

1. A 2,000 lb. ton.
- II. A 100 lb. cwt.

Dr. LEWKOWITZCH agreed with Mr. Lupton in condemning the hydrometer scales in use, Twaddell's degrees as meaningless, and Beaumé's several scales as entirely irrational.

He inquired why pounds should be preferable to kilos. He contended that in practice there was a greater liability to error by using the English measures (*e.g.*, converting pounds into quarters and hundredweights) than in the metrical system, where only the ordinary mistakes made in adding were possible.

The contention that the kilo. was not exactly what it pretended to be was merely sentimental; probably 100 years hence further research would show corrections to be necessary of which we had at present no knowledge.

With regard to the difficulty of effecting the change, he recollected the transition stage in Prussia; the system was first introduced in the schools, and was rapidly adopted in commercial circles.

So far as he had studied them in the short time allowed, Mr. Lupton's proposed measures appeared good. The idea of making the pound equal to half a kilo. was that adopted by the Zollverein in 1858, and this measure made the transition to the kilo. easier.

He would prefer to use 0° C. rather than 17° as the standard temperature, and so obviate the errors due to incorrect calibrations of a thermometer.

Mr. PROCTER suggested that the reason why the metrical system had not come into use was that it had not been taught largely in schools, although it was a legal (allowed) measure and of much greater importance than many of the extraordinary measures taught. By teaching the metrical system to children they would be able to compare the two systems and would doubtless become dissatisfied with our present measures. He would suggest as practical reforms that the names of the metrical units could be shortened, and the denomination written directly after the whole

number and before the decimal figures, to avoid errors in the decimal place, *e.g.*, instead of 13·576 kilos, write 13 k. 576, a method used in Germany.

Professor SMITHIELLS also remarked that the metrical system was too seldom taught, even in schools bearing a good reputation, and he seldom found a new student who had any real idea of the magnitude concerned. He thought the effect of teaching it, as opposed to our own irrational system, would be beneficial, the system being logical and concise, and therefore tending to clearness of thought. He believed the introduction of a new system would be largely dependent on philanthropic and public-spirited endeavour on the part of those anxious for the convenience of their fellow creatures and in the pressing exigencies of business.

He considered the use of "proof" spirit and irrational hydrometers by the Excise Department to be a disgrace to the country.

He thought certain reforms, such as the introduction of rational hydrometers, the doing away with the local variations of the stone weight, and the adoption of the 2,000 lb. ton, should be immediately attempted.

As to Mr. Lupton's measures, he doubted whether it would be easier to adopt them than the metrical system.

Mr. G. W. SLATTER, in reference to hydrometers, remarked that he had found them so faulty in graduation that he always used specific gravity flasks or the hydrostatic balance.

Mr. LUPTON, in replying, said that he had chosen 17° C. as his standard because for ordinary work this would involve no correction for temperature. When the standard was fixed at 0° C., there were no thermometers in the market sufficiently accurate for taking the ordinary temperature, whereas now a 5s. instrument would be exact enough for ordinary work.

The pound was proved to be a more practical unit than the kilo. The German "pfund" and French "demikilo." were more extensively used in retail trade than the kilo.

His scheme was merely a rough draft, and he was surprised that it had not been more severely criticised.

Meeting held in the Philosophical Institution, Edinburgh, on Tuesday, February 2nd, 1892.

PROFESSOR CRUM BROWN, D.Sc., F.R.S., IN THE CHAIR.

THE PROPERTIES AND MANUFACTURE OF CELLULOSE.

BY WALTER HODGEN, F.C.S.

CELLULOSE is a frank forgery of many of the auxiliaries of civilised life. Its existence depends on the closeness of its resemblance to what is scarce, and, in consequence, costly.

The methods necessary to produce so close a resemblance to the real article cannot be followed out without considerable cost, and it is necessary to bear in mind that the cheapness of really good articles in cellulose is only relative to the value of the originals. Of these latter, perhaps ivory is the most important, and the decline in the supply necessarily tells heavily in favour of this department of the imitative industry; and, certainly, no better substitute than cellulose has as yet been found. But, indeed, it may generally be stated, as the specimens exhibited will show, that many of the results obtained, besides ivory, such as tortoiseshell, coral, amber, &c. resemble so closely the article copied that only experts can detect the difference.

In the case of the imitations to which I have hitherto alluded, the material is in a hard state, but it is also made in a more pliable form, which is used extensively in the manufacture of collars and cuffs, resembling closely when well made those in linen, the appearance of the threads and stitches being effectively produced.

The discovery of cellulose is said to have been made by a Mr. Hyatt, Newark, United States, but a patent for a similar material was taken out by an English chemist, the late Alexander Parkes. There can be no doubt that the latter produced a material corresponding in every respect to cellulose, which he named "Parkesine."

Cellulose is made from cellulose, which having gone through a nitrating process is dissolved by suitable solvents and then dried. Cellulose being, therefore, the base of the manufacture, naturally comes to be considered first. It has been defined, in a few words, as "the residue from the exhaustive alternate treatment of vegetable tissues, with alkaline solvents and weak oxydants."

The substance of bleached cotton may be taken as the typical cellulose, the process of bleaching having removed the foreign substances with which the cellulose is associated in the plant. A neat and clean arrangement for the purpose of bleaching pulp is a good deal used by paper manufacturers and others in France, where, I may say, much of my practical experience has been gained. It is known as Hermite's electro-chemical process of bleaching, and a short description of the apparatus may be found interesting in this connection. The electrolyser consists of a bath made of galvanised cast iron. The negative electrodes are formed by a certain number of zinc discs upon two small rods or shafts, which turn round slowly. Between each disc are placed the positive electrodes, which are composed of platinum gauze fitted into ebonite frames, the platinum gauze being soldered to a piece of lead and perfectly isolated. Each frame or positive electrode communicates by the piece of lead with a bar of copper which traverses the electrolyser, and the contact is made by means of a nut and screw, so that each frame containing the platinum gauze can be taken out while the machine is working. The copper bar to which are fixed the positive electrodes is in communication with the positive pole of the dynamo. The current is distributed in all the platinum electrodes, from which it passes, through the medium used, to the zinc discs forming the negative electrodes, and thence to the negative pole of the dynamo. Each electrolyser produces in twenty-four hours of work a power of bleaching equal to 125 kilos. (275 lb.) chloride of lime at 33 per cent. chlorine, and requires 8½ horse-power. The liquor is a mixture of chloride of magnesium, common salt,

and caustic soda, and is pumped through the electrolyser until the liquor is strong enough for use, when it is allowed to flow over the pulp to be bleached.

To turn, however, from the appliance to the material dealt with, cellulose has a specific gravity of 1.45. Its empirical composition corresponds to $(C_6H_{10}O_5)_n$, by which, together with its constitutional relationships, it is included in the group of carbohydrates. If examined through the microscope it will be found to be, when pure, a white translucent substance, but more or less opaque in the mass. It may be identified by its property of giving a blue reaction with iodine solution, in presence of, or after, treatment with dehydrating agents. When burnt—owing to the presence of mineral constituents—there is always an ash, however small, which usually takes the form of the original fibre. Another inorganic constituent, essential to the fibre under ordinary atmospheric conditions, is its hygroscopic moisture, or water of condition. The quantity usually present in cotton is 6 to 7 per cent., varying with the temperature and the dew point. Cellulose is a typical colloid, which, when fully hydrated, takes a gelatinous form. We are told that "in life there is a gradual and molecular dehydration of the tissues, and a progress from the gelatinous and amorphous condition to the specialised forms of maturity. Dehydration of a vegetable tissue, by exposure (after isolation) to air, but more especially by contact with alcohol, confers in a measure the properties which distinguish the fully elaborated cellulose and *vice versa*, the rehydration of the cellulose by artificial means may be regarded as in a limited sense the reversal of the process of growth."

Seeing that science has not yet found a direct practical means of rendering cellulose soluble, attention has therefore turned to nitrating the cellulose as a means to this end. True, cellulose has been dissolved by the ammonia-copper reagent (cupric hydrate in strong ammonia), in contact with which the fibre gelatinises, and finally disappears on complete solution. There is, however, no value in this as a practical method. Messrs. Cross and Bevan have, it is said, discovered a process of dissolving it, but no details of the process are available. The nitration process has, in consequence, been accepted as the only practical means of obtaining the desired object.

Pure cellulose, then, having been got in a suitable form, such as cotton or specially prepared paper, the manufacture now divides itself into three stages:—

- (1.) The production of the pyroxylin.
- (2.) The treatment of this compound with solvents in order to make it plastic.
- (3.) The drying process.

First, then, the *Production of the Pyroxylin* is accomplished in the following manner:—To avoid weakening the mixed acids more than is necessary and increasing the temperature, the cellulose must be as dry as possible. This having been seen to, the material is now ready for the conversion process. The nitrating shed is fitted with acid-mixing tanks, reservoirs for stocks, pots for the nitrating process, and washers. Weighed quantities of the cellulose are plunged into the mixed acids contained in earthenware pots. Nitric acid of moderate strength is used (1.38 to 1.45 sp. gr.) so as to avoid the formation of higher nitrates, the dinitro-cellulose being what is wanted. Sulphuric acid of 1.68° Tw. is employed. The temperature is from 70° to 90° F., according to the state of the acids. After about 20 to 30 minutes the cellulose is chemically converted into pyroxylin or nitro-cellulose, water being at the same time formed in the reaction—

The mixed acids are now run off and the pyroxylin allowed to drain for a minute or two, after which hydraulic pressure is employed so as to squeeze out as much of the acids as possible, these being valuable for future use when brought up to the necessary strength. The cake thus formed is then taken to washers arranged so as to break it up quickly, after which it is thoroughly washed in clear water in a succession of tanks. Bleaching—the next process—is done, either with chloride of lime or permanganate of potash. The water is allowed to drain off, and the

pyroxylin is further freed from it by a hydro-extractor, after which it is chopped into small pieces and the rest of the water got rid of by hydraulic pressure.

(2.) *The Treatment of the Pyroxylin with Solvents.*—Pyroxylin is not soluble in alcohol alone, but is readily soluble in a mixture of alcohol and camphor, and this is the solvent generally adopted. A mixture of this is therefore made and sprinkled over the pyroxylin in close boxes, the solvent being sparingly used on account of the cost. Having been allowed sufficient time to soak thoroughly into the mass the product is cut out of the boxes in pieces, and placed on rollers gently heated. Here it undergoes, thoroughly, a kind of kneading process, until it is uniform, when it is cut away from the rollers in sheets of the desired size and thickness. This process goes on until a sufficient number of sheets is obtained, when they are piled one above the other, and the whole pressed into a solid block by means of a hydraulic press. The block thus formed is next taken to a planing machine, specially constructed and beautifully adjusted, so that a sheet may be cut from the solid block of celluloid as thin as note paper. On this machine the block is placed and cut up into the thickness required, whether it be thin sheets for the manufacture of imitation linen, or thick ones for knife handles or other purposes.

(3.) The third and last process, that of *Drying the Material*, may be described in a few words. The sheets having been cut are placed in a heated chamber, where they are allowed to remain from one day to six months, according to the thickness and nature of the stock. When ready the celluloid is worked, by means of intricate machinery, as well as by the more ordinary methods of carving, turning, and moulding, into an endless variety of articles of both beauty and use.

As regards the colouring and markings, it is sufficient to say that they are the results of elaborate experiments and processes which are jealously safeguarded as secrets of the industry.

It may be added in conclusion that celluloid has a specific gravity of from 1.30 to 1.45, according to the degree of pressure to which it is subjected and the quantity of pigments in its composition. It is not affected by weak acids, and is water- as well as air-proof.

DISCUSSION.

DR. J. R. PATERSON said that he would like to ask the following questions, viz.:—If the production of the article to imitate ivory was a secret? If the substance was easy to work on the lathe? Did it work as well as vulcanite? And if any efforts had been made to obtain a solvent that would do away with the smell of the article?

THE CHAIRMAN asked if when the gelatinous mass was made into such a cake as that shown, it shrunk much in the process of drying; and if the manufactured article got softer as it got older, for as it smelt strongly of camphor it was bound to be continually losing that commodity?

MR. E. C. C. STANFORD said that they were very much indebted to the author for this paper if it were only from the fact that there could be so few chemists who knew anything about the manufacture of celluloid. He supposed there was no doubt that it really was a mixture of collodion and camphor. One great drawback it had was its inflammable nature. Some time ago, one of the principal American manufacturers of this article (he believed there was only the one manufacturer in the United States) wrote to him sending some fine samples, one of great transparency, and he said he could introduce the article very largely for windows, &c., which could not be broken; but the one great difficulty he had was that if you put a candle to it the whole thing burst into flames. He wanted to know if some method could not be adopted to prevent that? He (Mr. Stanford) would therefore like to ask Mr. Hogben if this substance could not be denitrated, for if it could, then it would be a most valuable article for many things. He would call particular attention to the imitation of ivory

shown, because that was one of the most difficult things to imitate, as it was produced by successive layers of natural growth, and the sample was beautifully done.

Dr. A. P. AITKEN asked if celluloid was harder than horn.

Mr. W. I. MACADAM said he had seen some celluloid balls, similar to the sample shown, which on standing in a shop window had completely collapsed.

Mr. J. LAING asked if bottles had been manufactured from this material, and if it would be suitable for lining trunks. Also what was the size of the largest sheet made, and if the sheets could be joined together.

Mr. HOBGEN, in reply to Mr. Paterson, said (1) the imitation of ivory was a secret; (2), the substance was easily worked on the lathe; and (3) a solvent had been obtained to do away with the smell, but there were practical difficulties attending its use. With reference to the Chairman's questions—(1), the gelatinous matter did shrink until it was dried in the stoves; and (2) yes, the manufactured article got harder as it got older. In regard to Dr. Aitken's question, celluloid was harder than horn. As to Mr. Macadam's statement about the balls he had seen collapsing, perhaps the reason of this shrinking was that they had been made too thin. Then, in reply to Mr. Laing, bottles had not been made from celluloid, but he fancied it would be quite suitable for the lining of trunks, if its inflammability were not an objection. The largest sized sheets that were made were 4 ft. long \times 20 in. wide, and these could easily be joined together. Lastly, in reply to a question by the Chairman, he said that it was only a thin layer of celluloid that was put upon billiard balls.

Meeting held at the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, March 1st, 1892.

MR. E. C. C. STANFORD IN THE CHAIR.

THE LATE PROFESSOR DITTMAR.

THE CHAIRMAN said that since their last meeting the hand of death had again been busy among them, and had taken from their midst their valued friend Professor Dittmar. He need not say that in his death they had lost not only one of their colleagues, but a man of eminent position in science, and the committee had prepared the following resolution, which they proposed to transmit to Mrs. Dittmar:—"The Committee of the Scottish Section of the Society of Chemical Industry hereby record their deep sense of the great loss the Society has sustained by the death of their late colleague, Professor Dittmar, a loss which will be felt wherever the science of chemistry is known. They desire to express their sincere condolence and deep sympathy with his widow and family in their affliction."

THE PREPARATION OF PURE PHOSPHORIC ACID FROM PHOSPHATE OF SODA, WITH AN ACCOUNT OF SOME EXPERIMENTS ON THE PHOSPHORUS-NITRIC ACID METHOD OF MANUFACTURE.

BY GEORGE WATSON, F.C.S.

Pure phosphoric acid is a substance used to a certain extent in pharmacy, constituting, as it does, one of the ingredients of metallophosphatic syrups of various kinds. The acid, usually sold for the preparation of these syrups, is a thick colourless liquid of a sp. gr. of 1.750, containing about 89 per cent. of orthophosphoric acid. It must conform to all the tests of the British Pharmacopœa, that is to say, it must be free from notable quantities of lime, iron, magnesia, or other basic substances. It must not coagulate albumen or produce a precipitate when warmed with mercuric chloride solution. Neither may it contain nitric or sulphuric acids, and it must be absolutely free from arsenic.

It is commonly prepared, so far as I am aware, from yellow phosphorus, but as this latter substance is itself made from crude phosphoric acid by means of carbonaceous reduction, it is evident that the preparation of pure phosphoric acid from phosphorus, viewed in conjunction with the phosphorus manufacture, is essentially its preparation from crude phosphoric acid, the intermediate production of phosphorus being simply a method of eliminating the various impurities inherent in the crude acid.

As phosphorus is a somewhat expensive article, however, although less so now than formerly, the possibility of doing away with its use and of preparing the pure from the crude acid by some cheaper process, naturally suggests itself.

Some years ago, therefore, I made some experiments with this object, and although I was unsuccessful in working out a paying process, yet as I had also carried out some experiments on the phosphorus-nitric-acid method of manufacture, I thought a description of the whole might be of interest to the Section.

After several abortive trials, which it is needless to describe minutely, such as the lixiviation of "superphosphate" with methylated alcohol, the ignition of ammoniac phosphate, the boiling of ammoniac phosphate with hydric nitrate and with "aqua regia," it occurred to me that in the treatment of sodic phosphate with hydric chloride, there existed a reaction which was somewhat hopeful. For hydric chloride, in its affinity for bases, is, at ordinary temperatures, one of the most powerful acids known, while hydric phosphate is a relatively weak one. On consulting tables of the relative affinities of acids it is seen that the strengths of these two acids are in the ratio of 1 to 0.25. In other words, if, for example, a formula weight of monosodic phosphate in dilute aqueous solution be mixed with a formula weight of hydric chloride, the soda divides itself between the two acids in proportion to their affinities. If the amount of base existing as chloride when equilibrium is attained be represented by the symbol "*a*" then the total amount present being one equivalent, $1-a$ represents the amount retained by the hydric phosphate, and the ratio $\frac{a}{1-a}$ is a measure of the relative strengths of the two acids. In the case under consideration this ratio is equal to $\frac{1}{0.25}$, from which the value of "*a*" is found to be 0.80, or 80 per cent. of the soda now exists in solution as chloride. Further, as sodic chloride is practically insoluble in a saturated solution of hydric chloride, then by saturating the solution with this gas, one would expect to have all the dissolved sodic chloride precipitated, and the relative amount of hydric chloride being simultaneously much increased a further decomposition of the remaining 20 per cent. of sodic phosphate might be expected to take place, resulting in the liberation of an increased proportion of hydric phosphate. As the use of dilute solutions, however, was out of the question on the ground of economy,

my first practical experiments were confined to gassing melted crystals of disodic orthophosphate with hydric chloride. A preliminary experiment, in which 4 lb. of pure disodic phosphate, mixed with a little water, were used, showed that the soda was virtually all separated by this treatment; the resulting liquor on draining off from the sodic chloride being found, on analysis, to contain soda equal to only 0.705 per cent. of the syrupy hydric phosphate (sp. gr. 1.750) actually present. I then proceeded to try the process on a larger scale, the following being a few typical experiments.

Thus, 65 lb. of pure disodic phosphate, melted and gassed with hydric chloride, weighed after saturation 90 lb. On settling, syphoning and draining off the clear supernatant, 48 lb. of liquor were obtained, which on evaporation gave 12 lb. of syrupy hydric phosphate, corresponding to a yield of 60 per cent. of the theoretical amount. The acid was found, on testing, to be quite free from all impurities with the exception of a small amount of soda similar to that mentioned above.

Another experiment, in which 63 lb. of sodic phosphate were used, absorbed 24 lb. of hydric chloride, while the liquor, drained off from the precipitated sodic chloride, weighed 53 lb. On evaporation of this liquor 13½ lb. of syrupy phosphoric acid were obtained corresponding to nearly 66 per cent. of the theoretical quantity.

In the next trial the proportion of hydric chloride was increased. To 67 lb. of melted sodic phosphate crystals were added 20 lb. of pure aqueous hydric chloride (sp. gr. 1.160), then the whole saturated with hydric chloride gas as before. Of this, 23 lb. were absorbed, an amount almost identical with that absorbed in the previous trials. On draining off, 80 lb. of liquor were got, giving, on boiling up, 15 lb. of hydric phosphate, equal to a yield of about 75 per cent.

Another experiment was then made in the following way: 70 lb. of sodic phosphate were melted and saturated with hydric chloride as before, the amount absorbed being 29 lb. while the liquor drained off amounted to 56 lb., and gave on evaporation 14 lb. of hydric phosphate, or two-thirds of the total amount obtainable. The residual salt was then digested with one gallon of water for a few hours. This liquor on draining off weighed 13½ lb. On saturation with hydric chloride it weighed 16½ lb., and gave 2 lb. of syrupy hydric phosphate. On digesting the original salt with a second gallon of water, 17½ lb. of liquor were produced, absorbing 4 lb. of hydric chloride gas and giving 1½ lb. of hydric phosphate, the total yield being thus equal to 81 per cent. of the theoretical.

In the two experiments first described, the weight of sodic chloride produced, supposing all the hydric phosphate to have been liberated, is 22½ lb., while the weight of liquor obtainable, if the sodic chloride had been obtained anhydrous, should have been 69½ lb. The difference between this weight and the mean weight of liquor actually drained off is therefore 19 lb. As this seemed a large amount of liquid to be held by 22½ lb. of sodic chloride, I was inclined to believe that a considerable portion of the sodic phosphate was not decomposed, but was simply thrown down as monosodic phosphate.

Consequently I then proceeded to examine the reaction more carefully on a small scale, using, instead of crystallised disodic phosphate, anhydrous sodic pyrophosphate and digesting it with definite weights of pure aqueous hydric chloride.

The sodic pyrophosphate used was made from the ordinary pure disodic phosphate of commerce by a further threefold crystallisation. The purified crystals obtained were then melted, filtered through paper, and the filtrate evaporated to dryness. The residue after powdering was then ignited, in successive small portions, to a red heat for about an hour. The hydric chloride used was prepared by distilling ordinary pure analytical acid and bringing the distillate up to the requisite strength by bubbling in well-washed hydric chloride gas. It was found, by alkaline titration, to contain 40.736 grms. of hydric chloride per 100 cc., measured at 12° C., while the specific gravity at the same temperature was 1.176, thus indicating 34.63 per cent. A specific gravity determination at 15° C. gave 1.174,

which from Kolb's table is equal to 34.45 per cent. of hydric chloride.

In carrying out an experiment, the pyrophosphate was always again ignited just before weighing out, and while still warm was again ground in an agate mortar. A weighed quantity was then placed in a dry stoppered bottle, a definite quantity of hydric chloride run in, and after inserting the stopper the whole shaken up at intervals and allowed to stand a prescribed time.

In the first experiment 10 grms. of pyrophosphate and 40 cc. hydric chloride were digested together for 24 hours, then the liquid filtered off through a funnel plugged with glass wool into a ½ litre flask, and the residual matter washed with methylated alcohol until acid free. The filtrate was then made up to the mark with water and the hydric phosphate estimated in 20 cc. by "magnesia mixture," after having boiled it for 30 minutes to ensure that all the pyrophosphoric acid was converted into the ortho form. The precipitate obtained weighed 0.3337 grm., equivalent to 7.365 grms. of hydric phosphate in the ½ litre. The total amount of hydric phosphate obtainable from 10 grms. of sodic pyrophosphate being 7.368 grms., this result is equal to 99.95 per cent.

Experiment No. 2 was similar to the above in all respects saving that 30 cc. of hydric chloride were used instead of 40 cc. The precipitate obtained from 20 cc. weighed 0.3356 grm., equivalent to a total of 7.407 grms. of hydric phosphate, or 100 per cent. The result of this experiment may be expressed symbolically as follows:—

or as a general expression representative of the complete decomposition of sodic pyrophosphate by the minimum of hydric chloride; we have—

in which n = a number less than 8.9. Other three experiments were then made to ascertain the value of n .

Experiment No. 3.—7.4215 grms. of pyrophosphate and 11.636 grms. of hydric chloride were digested 48 hours. As in this case, however, there might not be a sufficient excess of hydric chloride to prevent some of the sodic chloride from going into solution, 50 cc. of methylated alcohol were added before filtering off, the liquid being then filtered through paper into a litre flask, and the residue washed acid free with alcohol as before. The filtrate was then made up with water to the mark, and 50 cc. taken for the determination of hydric phosphate. The precipitate weighed 0.2225 grm., equal to a total of 3.929 grms. of hydric phosphate in the litre, or a yield of 71.811 per cent.

Experiment No. 4.—10 grms. pyrophosphate were digested with 17.5 grms. hydric chloride for 48 hours, diluted with alcohol, filtered off, and the filtrate made up to a ½ litre. The precipitate obtained from 20 cc. weighed 0.2955 grm., equal to a total of 6.522 grms. of hydric phosphate, or 88.518 per cent.

Experiment No. 5.—In this experiment 10 grms. of pyrophosphate were digested with 16 cc. hydric chloride for 66 hours, then diluted with alcohol and treated as before, the filtrate being made up to a ½ litre. The estimation of hydric phosphate in 20 cc. gave a precipitate weighing 0.3315 grm. equal to 7.317 grms. of hydric phosphate in the ½ litre or 99.348 per cent.

In experiments Nos. 3 and 4, an interesting relation between the hydric phosphate set free and the hydric chloride required for its liberation exists, which enables us to calculate the value of n . Thus in experiment No. 3, the weight of anhydrous hydric chloride contained in the 11.636 grms. of aqueous acid taken is 4.0190 grms. If from this weight there be subtracted the weight of dry hydric chloride required to combine with half the soda in the 7.4215 grms. of pyrophosphate (*i.e.*, the amount necessary to transform the normal sodic pyrophosphate into disodic pyrophosphate or possibly monosodic ortho-

phosphate) there is obtained the number 1·9823. Multiplying this by 2 gives 3·9646, a number practically identical with the weight of hydric phosphate found to be liberated (3·929 grms.). From this experiment it is seen that the hydric chloride acts with two functions: firstly a portion is used to saturate half the soda in the pyrophosphate, then the remainder acts on the resulting salt and sets free twice its weight of hydric orthophosphate. Examining experiment No. 4 in the same way, a similar result is arrived at. Thus deducting from the weight of hydric chloride used (6·0444 grms.) the weight required to combine with half the soda of 10 grms. pyrophosphate (=2·7443 grms.) there is obtained 3·3001, which multiplied by 2 gives 6·6002, a number virtually identical with the weight of hydric phosphate bound to be liberated (6·522 grms.).

Assuming then this relation to hold for all quantities of hydric chloride, and calculating the least weight necessary to completely liberate the hydric phosphate from 10 grms. of pyrophosphate, there is obtained 6·4283 grms. of dry hydric chloride which is equal to 15·8 cc. of the aqueous hydric chloride, used in these experiments. In experiment No. 5, 16 cc., or only 1·3 per cent. more than this, was found to liberate all the hydric phosphate from this weight of pyrophosphate, so that the statement made may be taken as true. The following equation represents therefore the final distribution of matter when equivalent weights of sodic pyrophosphate and aqueous hydric chloride are digested together at the ordinary temperature under the conditions specified:—

while the expression representing the complete decomposition of the pyrophosphate by the minimum of hydric chloride is—

The symbol "aq." signifies, of course, the amount of water contained in the aqueous hydric chloride.

This reaction was not found to constitute a paying process for the manufacture of phosphoric acid. The washing out of the acid retained by the salt by means of alcohol was inadmissible, while the use of hydric chloride solution for this purpose would have led to the necessity of considerable evaporation and the recovery of the hydric chloride used if the costs were to be kept within reasonable limits. Further, it was found that the sodic phosphate had to be quite free from sulphates, otherwise the soda was not completely separated. The sodic sulphate thus left in the syrupy acid had, when in small quantities, the effect of imparting a gelatinous consistency to it, while in some cases when the amount was larger the acid became quite solid on cooling. In other cases again the acid was apparently all right when at first prepared, but on standing for some days it became milky from the separation of sodic sulphate. This precipitate of sodic sulphate took a long time to settle, and the separation not being complete the clear supernatant acid had always a gelatinous appearance. Only when the sodic phosphate was quite free from sulphate was the acid suitable.

The practical experiments described above were made in the early part of the year 1888. After they had been completed there appeared in the Chemical Society's Journal, 54, 321, an abstract of a paper by A. Bettendorff, published in the Zeits. Anal. Chem. 27, 24—26, in which this reaction is made use of for the detection of sodium in glacial phosphoric acid. According to this chemist 98·5 per cent. of the sodium of sodic pyrophosphate is separated as chloride on digesting the pyrophosphate with aqueous hydric chloride of 1·19 sp. gr. He also suggests this reaction as a convenient method of preparing hydric phosphate directly from sodic phosphate. I find also that a similar process has been proposed by A. Joly (Compt. Rend. 102, 316—318) in the case of monammonium phosphate, the liquor obtained, however, after separation of the ammonic chloride, being heated by him with successive

portions of hydric nitrate in order to complete the expulsion of the remaining ammonia as well as the hydric chloride.

I have now to describe the experiments made on the phosphorus-nitric-acid method of manufacture. As this is an oxidation process, however, it may be of interest to review shortly, in the first place, the results obtained by other chemists on the oxidation of phosphorus by various means.

Phosphorus is not so easily oxidised into the state of pentoxide, or of hydric phosphate as one might imagine from its great inflammability. It is true that when burned in abundance of air or oxygen, the pentoxide is the only final product, but when it is burned in a confined air space, as, for example, under a bell-jar, a considerable amount of the trioxide is also produced in addition to a certain quantity of the suboxide P_2O_3 . (See also this Journal, 1885, 574, et seq.).

Thorpe and Tutton have shown (Trans. Chem. Soc. 57, 545—573) that when phosphorus contained in a combustion tube is burned in a comparatively rapid current of air, in addition to the formation of the suboxide, a certain quantity of the trioxide is also formed, the oxidation being, however, under the conditions of their experiments, a relatively feeble one, if compared with that taking place in the open air. On the other hand, according to the same chemists, phosphoric oxide is the only oxide formed when phosphorus glows in the air at the ordinary temperature (Chem. Soc. Trans. 49, 833) while they also prepared from the products of the slow oxidation of phosphorus in dry air an oxide of the formula P_2O_4 (*loc. cit.*). This oxide they consider to be the true tetroxide of phosphorus, and not the anhydride of hypophosphoric acid ($\text{H}_4\text{P}_2\text{O}_6$) obtained by Salzer, by the slow oxidation of phosphorus partially immersed in water.

Again, J. Corne (J. Pharm. Chim.), by heating phosphorus to 75° C. in a solution of cupric nitrate, found that hypophosphoric acid was formed while J. B. Senderens (Compt. Rend. 104, 175—177) states that amorphous phosphorus when heated with solutions of argentic or cupric nitrates gives in the one case a precipitate of silver, in the other a precipitate of copper phosphide, the phosphorus being at the same time oxidised into hydric phosphate.

It is also known, that on dissolving yellow phosphorus in dilute hydric nitrate, a certain amount of hydric phosphite is produced which amount is greater at the initial stages of the solution (Fresenius' Qual. Analyses, 9th ed., 176), but no determinations of the relative proportions of the two acids seem to have been made. I therefore thought it would be of interest to examine this point.

For this purpose a flask of about 1 litre capacity, having a short, thick walled neck, was taken, and a glass condensing tube of about three feet in length and three-quarters of an inch bore fitted to it by grinding. An indefinite weight of yellow stick phosphorus (usually about 60 grms.) was then placed in the flask and 500 cc. of dilute hydric nitrate run in. The condensing tube was then inserted, and the contents heated up till the reaction was started, the reaction being then kept going for the prescribed time, external heat being used when necessary. The phosphorus used was a good sample of commercial stick phosphorus, containing a little arsenic, and the hydric nitrate used was prepared by distilling pure analytical acid and diluting the distillate to a sp. gr. of 1·223. A titration of this acid with standard soda showed that it contained 35·77 per cent of HNO_3 . This acid was used in experiments Nos. 1, 2, and 3, while in the remainder weaker acids made from it by dilution were used. At the end of an experiment the solution was diluted to a convenient strength and two comparable volumes taken for the estimation of total phosphorus and that existing as hydric phosphate. The hydric phosphate was always precipitated as ammonio-magnesian phosphate directly from the solution after having diluted it to a volume of 250 cc. The total phosphorus was estimated in its portion of the liquid after it had been evaporated to a film with 60 cc. of nitro-hydrochloric acid, this treatment being found to effect a complete oxidation of the hydric phosphite. The annexed table contains the results of these experiments.

TABLE SHOWING THE ACTION OF HYDRIC NITRATE ON YELLOW PHOSPHORUS.

No. of Experiment.	Strength of Hydric Nitrate.	Time of Cohobation.	Weight of $\text{Mg}_2\text{P}_2\text{O}_7$ Precipitate obtained = H_3PO_4 produced.		Weight of $\text{Mg}_2\text{P}_2\text{O}_7$ Precipitate obtained = Total Phosphorus dissolved.		Ratio of Phosphorous to Phosphoric Acid.	Remarks.
			Cc.	Grm.	Cc.	Grm.

From these experiments it is seen that as the strength of the hydric nitrate is reduced, the ratio of the phosphorous to the phosphoric acid alters until in experiments Nos. 6 and 7 it corresponds to that of equal weights. In the two last experiments, in which still more dilute hydric nitrate was used, the proportion of hydric phosphite formed is slightly greater, although not to any remarkable extent, the ratio still practically being that of equal weights. Further, from the first five experiments, in which the strongest acids were used, it is seen that the effect of reducing the time of cohobation is also to increase the proportion of hydric phosphite formed. These show that in addition to the fundamental reaction, a secondary one is going on, in which the hydric phosphite formed in the primary reaction is being oxidised into hydric phosphate. The primary reaction, therefore, must correspond to the formation of some larger proportion of hydric phosphite than that found in experiment No. 3 for example. If, then, the effect of diluting the hydric nitrate be to eliminate this secondary change, the ratios found in the last four experiments probably represent the fundamental reaction, and these ratios correspond to the formation of equal weights of hydric phosphite and phosphate. From a consideration of the results obtained by the chemists already mentioned it might have been expected that the primary reaction would have been one in which equivalent weights of the two acids were formed, corresponding to the ratio $\frac{\text{H}_3\text{PO}_3}{\text{H}_3\text{PO}_4} = \frac{1}{1.15}$, but in only one experiment (No. 5) is this relation at all approximated to, and this experiment does not represent a state of equilibrium. At the same time, it is possible that this may be the principal reaction, and that the excess of hydric phosphite is due to another hye reaction. For, in boiling yellow phosphorus with hydric nitrate, little globules of phosphorus are thrown up to the surface of the liquid and there undergo a slow combustion in the atmosphere of the flask, with the result that the upper part of the vessel becomes filled with white fumes. In all these experiments these fumes were formed and issued from the end of the condensing tube into the air. In nearly every case a portion condensed in the cool end of the tube as a white film, while in experiment No. 8 a series of lambent flames passed continually down the tube from the orifice. At the conclusion of experiment No. 1 this film was washed into a small beaker with cold water. It did not wholly dissolve in the cold even after digesting for half an hour, but on boiling it went into solution with separation of a pale yellow powder. The solution, when tested qualitatively, showed the presence of both phosphate and phosphite, the latter so far as could be judged in larger amount. The white fumes, therefore, evidently consisted largely, if not wholly, of phosphorous oxide. On the other hand, if the equal weight ratio be due to this secondary reaction, it is remarkable that the ratios found in experiments Nos. 6 to 9 do not show a greater variation among themselves than they do. On the whole, I think

that the balance of evidence, so far as it goes, is in favour of the statement that the primary reaction taking place is one in which equal weights of hydric phosphite and hydric phosphate are formed, but further experiments are necessary on this point.

In carrying out this reaction for the preparation of phosphoric acid a few points have to be attended to. As the formation of hydric phosphate from phosphorus, oxygen, and water liberates a much larger amount of heat than the corresponding formation of hydric nitrate, the reaction between phosphorus and hydric nitrate is an exothermic one. The speed of the reaction, and therefore the period of time in which this heat is evolved, depends on the concentration of the hydric nitrate and the extent of phosphorus surface exposed to it. Consequently, if the oxidation is being done in a glass retort cooled only by radiation, and the amount of heat generated be greater than can thus be dissipated, the excess is spent in distilling over water from the retort. The hydric nitrate becoming in this way continually stronger, the reaction may become more and more tumultuous, until, when all the liquor has been driven over, the temperature has risen so high that any phosphorus still present begins to distil, and the vessel may be broken. The strength of the hydric nitrate and the extent of phosphorus-surface exposed to its action must therefore be such that this does not happen. The strength given in the text-books for the hydric nitrate is the best one, viz., an acid of about 1.200 sp. gr. From my own experience, it is not advisable to use an acid of greater gravity than 1.250 nor one much below 1.200, so that the limits are somewhat narrow. By increasing the surface of the phosphorus, however, the speed of the reaction can be safely accelerated to a certain extent. Thus, using 1 lb. of phosphorous and 12 lb. of hydric nitrate (sp. gr. 1.215), and reacting for one working day, 2 $\frac{1}{4}$ lb. of syrupy phosphoric acid were produced. With the same weight of hydric nitrate and 1 $\frac{1}{4}$ lb. of phosphorus, and reacting for as nearly as possible the same time, 3 lb. of phosphoric acid were obtained, while 1 $\frac{1}{2}$ and 1 $\frac{3}{4}$ lb. of phosphorus gave under the same conditions 3 $\frac{1}{4}$ and 3 $\frac{1}{2}$ lb. nearly of phosphoric acid respectively.

When working the process continuously, it is not advisable to continue the oxidation until all the phosphorus has been dissolved as the reaction becomes very slow when the phosphorus becomes small in amount, but it is better to pour off the liquor at the end of a day's working and re-start with an augmented amount of phosphorus and a new quantity of hydric nitrate.

The liquor obtained in this way, which still contains some hydric phosphite, is then evaporated in glass retorts until all the hydric nitrate has been expelled, by which time the oxidation is complete. The oxidation of this remnant of hydric phosphite seems to take place in stages, as during the concentration the liquid, which is at first nearly colour-

less, becomes brown, and evolves nitrous fumes. It then becomes clearer until the concentration has proceeded further, when it again becomes brown, and evolves more nitrous fumes, and so on, the final oxidation taking place when the evaporation is almost finished. The heating is then continued until the liquid stops bubbling, and is kept hot for a short time in order that the acid may be rendered quite colourless. The strong acid at this temperature has a corrosive action on glass, so that the heating must not be too long continued, otherwise, the temperature rising, the retort may be spoiled, but even with all care the glass in course of time becomes so thin that the retorts have to be laid aside.

The phosphoric acid obtained still contains the arsenic originally present in the phosphorus from which it has to be purified. This is done by precipitation as sulphide. A suitable quantity of the acid is diluted with water to a gravity of from 1.200 to 1.250, and heated up in a stoneware pan to a temperature of about 70° C. A stream of hydric sulphide is then passed in until the arsenious sulphide, which at first imparts a uniform yellow colour to the liquid, separates out as a precipitate. The liquor is then allowed to stand about 18 hours until cold, when it is again well gassed with hydric sulphide. After standing till the next day it is filtered through a sufficient thickness of calico, and the filtrate, which is now free from arsenic, evaporated to a gravity of 1.750.

This concludes my experiments on this subject at the present time, but when time permits I intend to examine the action of aqueous hydric chloride on several other phosphates, phosphites, and hypophosphites of metals which form chlorides insoluble in hydric chloride, and will have pleasure in placing the results before the Society at a future date.

DISCUSSION.

The CHAIRMAN said that a record of experiments of this sort upon any point in chemistry—even if, or perhaps especially if, they proved failures—was very valuable. He gathered that in the experiments related in the first part of the paper the phosphoric acid was made pure, with the exception of the presence of soda. Perhaps that was not so bad an impurity as others. Arsenic was often present, and that was worse. This impurity prevented the use of such phosphoric acid in medicine.

Professor E. J. MILLS asked if Mr. Watson had tried the experiment of simply passing a current of air through the nitric acid during oxidation, and, if not, he might be allowed to suggest it to him.

Mr. C. A. FAWCETT said that Mr. Watson's paper, coming as it did from a manufacturer of pure acids, would no doubt be a valuable contribution to the literature on the subject. He had occasionally to use phosphoric acid, and found it difficult to obtain, with even a moderately small percentage of iron, at a reasonable price. The author had stated that the acid he had examined contained notable quantities of iron: would he kindly say what it was in per cent. Some phosphoric acid that he had seen was more like a solution of phosphate of iron than phosphoric acid.

Mr. W. G. O'BRIEN asked: In what vessels did Mr. Watson evaporate his phosphoric acid from the dilute to the syrupy condition? He had made some experiments on a semi-manufacturing scale with a view to produce pure phosphoric acid, from bone-ash, Florida-rock, and Bull-river-rock, in the course of which he found the phosphoric acid to act very severely on the metallic vessels employed—glass or porcelain being too small for the purpose. Lead, copper, and tin were tried under similar conditions, lead lost 2.0 per cent., copper 0.4 per cent., and tin 5.1 per cent., thus showing that neither of these metals was very well adapted to the purpose. He fully agreed with Mr. Fawcett in saying that the preparation of a really pure phosphoric acid was not an easy matter, as he found, when working with natural phosphates, that the elimination of all traces of CaO and SO₃ was to be very difficult, and the acid so obtained almost invariably darkened in colour on obtaining a specific gravity of about 1.5. He, however, found that a strong, though

really not pure, acid could be obtained in this way. He did not consider a process in which spirits were employed could be a financial success, and also thought the preparation of phosphoric acid from phosphorus by oxidation with nitric acid was a costly method. He had been told that a phosphoric acid, which he found to be comparatively pure, had been obtained from a superphosphate prepared from Florida-rock and sulphuric acid, but as his own results did not confirm this, he could not say if the statement were correct.

Mr. E. RODGER said that he understood Mr. Watson objected to the process of obtaining phosphoric acid by the oxidation of phosphorus in the usual way, because of the presence of arsenic. He did not see what advantage the process of oxidising with nitric acid had over the ordinary one, as in both cases the arsenic was oxidised, and so the phosphoric acid was contaminated; but Mr. Watson had doubtless some good reason for making use of nitric acid. Regarding the manufacture of phosphoric acid from phosphate rock, he might say that if pure sulphuric acid were used to decompose phosphate of lime, a very decently pure phosphoric acid was obtained straight away, which did not contain either arsenic or soda.

Mr. WATSON in reply said that in regard to the preparation of phosphoric acid, there were two qualities made, a pure quality used solely for medicinal purposes and a crude or impure one made in larger quantities and used, he believed, in certain processes of the sugar industry. The paper referred only to the former, and he had no experience of the manufacture of the latter. He used glass vessels in the concentration, which were quite suitable for the quantities required; but even for the concentration of larger quantities he thought that the use of glass retorts, such as those used in vitriol concentration, should be feasible. No metal dishes, with the exception of platinum ones, could be used in evaporating phosphoric acid to a sp. gr. of 1.750. When he said that the acid must be free from notable amounts of iron, lime, &c., he meant that it must fulfil the tests of the British Pharmacopœia, and although no definite percentages were there stated he supposed that a half per cent. of total impurity, exclusive of arsenic, would be the limit. Arsenic could not be tolerated. He had not tried the experiment suggested by Professor Mills, but had no doubt it would recover a large proportion of the nitric acid. Mr. Rodger was mistaken in saying that he objected to the process of obtaining phosphoric acid by the oxidation of phosphorus in the usual way, and as he (Mr. Rodger) said, the arsenic being derived from the phosphorus, it was certain to appear in the phosphoric acid, no matter by what method the phosphorus was oxidised. Hence it had to be eliminated afterwards, and he found that precipitation as sulphide in the way described was a convenient way of doing this. Phosphoric acid made from rock phosphate and sulphuric acid could no doubt be obtained free or nearly so from lime, but it would still contain the alumina, magnesia, and oxide of iron present in the mineral phosphate, and these substances, especially alumina, were objectionable in a pharmaceutical phosphoric acid. He had recorded his experiments on the nitric acid method of oxidising phosphorus (and, indeed, all the experiments described) simply in the hope that the description might be of interest to the members and not because he preferred the process as a practical method of making pure phosphoric acid.

Obituary.

EMERITUS PROFESSOR REDWOOD.

DR. THEOPHILUS REDWOOD, Emeritus Professor of Chemistry and Pharmacy to the Pharmaceutical Society of Great Britain, died on Saturday, March 5, at his Welsh home, Boverton, Glamorganshire, in the house where he was born eighty-six years and five days previously.

Dr. Redwood was very fond of his home at Boverton. It was a small estate belonging to his father, and was where he passed his boyhood. It came into his possession after the death of an elder brother, and for many years the Professor turned thither every summer vacation. His wife died there in 1868, and he is now buried beside her in Llanwit Major Churchyard. During the last two or three years he has spent the greater part of his time at Boverton, paying only occasional visits to London when important business required his attention at his laboratory. He had a little laboratory at his home; but his hobby at Boverton was to make improvements on his estate—gardening and such other country work as came in his way—for others as well as for himself. He was well known, and much loved and respected by his neighbours, poor and rich, for many miles round—his helpfulness and his unvarying kindness being often called into requisition.

Dr. Redwood was first introduced to the drug trade at Cardiff, and in that same town last August he appeared before pharmacists for the last time. His son tells us that he believes that occasion was the last on which his father took part in any public function of any kind. Very hearty indeed was the reception given to him when he stepped forward to second the vote of thanks to the President for his address. It was just seventy years ago, said the speaker, that he commenced his pharmaceutical studies in that town. He had a claim, therefore, to look upon himself as a Cardiff pharmacist. In those seventy years, he reminded his audience, Cardiff had grown from a little town with four or five thousand inhabitants, with neither docks nor railroads, to the great busy place with its 128,000 inhabitants, and its vast docks and industries.

Young Redwood went to the shop of his brother-in-law, Mr. Charles Vachell, who did a large general trade and also practised as an apothecary.

Some three years later a Quaker lady who knew John Bell, of Oxford Street, was staying at the house of young Redwood's father, and through her influence an opening was made for him in that celebrated pharmacy. Some four or five years after he had entered the house, and when he had arrived at the principal-dispenser counter, it was found necessary to enlarge the pharmacy. The firm offered a premium for the plan which should be approved by them for enlarging and remodelling the shop, and all in the place, partners and assistants, were invited to compete. Many drawings were sent in, but the one which received the prize was Redwood's. His design was approved in every detail, and though it involved some structural alterations, these were carried out exactly as described, and the shop as it now exists is almost the same as that which young Redwood planned.

While he was engaged in the business of John Bell & Co., the son of the chief, Jacob Bell, came into the establishment. Jacob Bell was four years younger than Redwood, and he had the sense to take him as his guide and instructor in pharmaceutical matters.

Redwood left Oxford Street and established a business of his own in Crawford Street. There he fitted up a small factory, and began the manufacture of some chemical and pharmaceutical products, devoting especial attention to the perfection of the preparation of extracts *in vacuo*. His business subsequently passed into the hands of Mr. Thomas Biggs, to whom succeeded Mr. Frederick Curtis, who removed it to Baker Street, and whose successors, Messrs. Jameson and Son, are the present proprietors.

In 1841 Jacob Bell commenced the organisation of the Pharmaceutical Society, and from that date till Mr. Bell's death, in 1859, Mr. Redwood was the thoughtful, painstaking, wise, but singularly unobtrusive supporter of the enterprise to elevate the status of the British chemist and druggist. Through those years Mr. Redwood was the organiser of the Society's scientific, and, to a great extent, of its educational work. Some Jubilee reminiscences, from Mr. Joseph Ince, show how the scientific work of the Society was done in its early days. There were excellent evening meetings, good papers were read, important processes explained, and there were several able men who could be relied upon to discuss whatever was brought forward. The Council appointed a committee to

provide for the evening meetings, but Redwood, as the scientific officer of the Society, communicated all papers. There arose complaints that Redwood was too much in evidence, and Mr. Bell, always anxious to encourage every one to take part in the common work, stepped into the background, and took his friend with him. The entire control of the evening meetings was handed over to the committee, and when the session of 1851-52 opened there was no paper and no suggestion, and October 1851 is a blank in the official records. Mr. Bell and Professor Redwood were requested to resume their original positions.

Mr. Redwood was appointed Professor of Pharmacy to the Society when the school was first founded, and when Mr. Fownes resigned, on account of ill-health, the Chair of Pharmacy was united with that of Chemistry. The laboratory, which was the first in this country specially arranged for giving practical instruction in chemistry and pharmacy, was planned from Professor Redwood's designs. The College of Chemistry, under Dr. Hofmann, and the Birkbeck Laboratory at University College, under Professor Fownes, followed soon afterwards, the latter of these being constructed on the same principle as that of the one in Bloomsbury Square.

Professor Redwood was for many years Secretary of the Chemical Society, and also of the Cavendish Society. His degree of Ph.D. was conferred upon him by the University of Giessen, at the special request of Liebig when he was resigning his professorship at that institution.

In 1847 Redwood edited and partly re-wrote a new edition of Gray's Supplement to the Pharmacopœia. In 1849 a further edition was produced, and as by this time there was scarcely any of the original left, it appeared as Redwood's Supplement. Subsequently he edited and adapted for English readers a work on practical pharmacy, which was published as "Mohr and Redwood's Practical Pharmacy." A great part of the English edition was new matter written by Redwood. Another important literary work which he undertook was the re-casting of Pereira's "Materia Medica." This work was done in collaboration with his colleague Professor Bentley. He assisted Mr. Bell to found the "Pharmaceutical Journal," and to conduct it until that gentleman's death in 1859. From 1859 to 1870 Redwood was himself the chief editor. When the first British Pharmacopœia was published, in 1864, it was found so unsatisfactory that the Medical Council was obliged to call in the aid of some pharmaceutical experts. Dr. Redwood and Mr. Warington, of the Apothecaries' Hall, were engaged to prepare a new edition.

For fullness of knowledge on pharmaceutical matters Dr. Redwood had, perhaps, no equal in this country. When he had to speak in public he was generally very deliberate, but always very clear, and his words were always exactly the correct ones. But when he had to reply to an attack on his work, he was at his very best.

Dr. Redwood was married in 1845 to Charlotte Elizabeth, the eldest daughter of the late Mr. T. N. R. Morson, but he had the great misfortune to lose her in 1868 after a long illness. He leaves six sons and two daughters. A younger sister of his wife, the widow of his half-brother, kept house for him at Boverton, and was with him at his death.

Dr. Redwood was public analyst for the county of Middlesex, for the London districts of Holborn and St. Giles, and for the borough of Finsbury.

The Redwood Scholarship founded in his honour by a general subscription some six years, when he retired from the active duties of his professorship, will after the present session be appropriately associated with the Research Laboratory.

To the majority of those who read this tribute, Dr. Redwood has always been an old man in years, though as young as the youngest in thought, in quickness of apprehension, in debate, and in cordiality. From his earliest days to his latest he seemed absolutely free from prejudices.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

On the Durability of Aluminium. C. Winkler. Zeits. f. angew. Chem. 1892, 69.

See under X., page 244.

PATENTS.

Improvements in Apparatus for Cooling, Heating, and Drying Liquid and other Substances. T. A. Shaw and J. Rushton, Bradford. Eng. Pat. 4597, March 14, 1891.

IN a closed chamber of rectangular section the inventors dispose a number of perforated plates horizontally, surmounted by a filter and a distributing plate. On opposite sides of the chamber, at alternate divisions between the plates, are fixed the inlets of pipes connected with main pipes through which air or steam can be made to enter as may be required, the surplus escaping through one or two outlets in the third side of the chamber. Two similar but smaller receptacles are placed at a lower level, one on each side below the main vessel, and these are similarly fitted up with partitions, pipes, and exits. The liquid to be treated enters by a pipe in the top of the larger vessel, passes over the distributing plate through the filter, and descends through the perforated partitions, being exposed on its way to the action of the steam or hot air, if it is a question of evaporating or heating, or to that of cold air if the liquid is to be cooled. Two outlets near the bottom of the chamber lead the liquid through suitable pipes to the two lower vessels, where it is similarly treated, issuing finally from the lower ends of these vessels in the heated or cooled state as required.

The patentees claim the arrangement described and shown, and the specification is accompanied by two sheets of drawings.—B.

Improvements in Chemical Fire Extinguishers. J. Haslam, Tonge. Eng. Pat. 4839, March 18, 1891.

THESE improvements relate to stoppers or covers for chemical fire extinguishers, with a view to prevent the escape of gas produced by the action of the carbonate or other solution, through the accidental application of heat or from some other cause when not in use. One of the arrangements is shown in the accompanying illustrations

IMPROVEMENTS IN CHEMICAL FIRE EXTINGUISHERS.

which will explain themselves. India-rubber or other pliable material is employed for making the joint at the mouth of the vessel, and is indicated in the drawings by the thick black lines.

The patentee makes five claims and illustrates five different devices.—B.

Improvements in Apparatus for Drying and Disinfecting Cereals and other Granular or Sub-divided Materials. G. Borgarelli, Turin, Italy. Eng. Pat. 5486, March 28, 1891.

THIS refers to an apparatus for drying grain in bulk by passing it slowly down a vertical chamber over partitions or diaphragms, which at the same time admit of air being passed through in the opposite direction.

Each diaphragm consists of a number of ridged parallel surfaces like small roofs or inverted troughs, with openings at the top capable of being regulated by means of slides worked from the outside. Or the openings may be on the sloping sides of the ridged surfaces in the manner of louvres, and the ridges are placed crossing each other in alternate diaphragms, whilst the openings through the tops or sides are also disposed in a way to cause the grain to descend in zig-zag fashion. From a plate over the uppermost diaphragms in the chamber depends a number of hopper openings through which the grain is admitted, and hoppers are similarly provided under the lowest partition for its removal. Above the lower hoppers the chamber is encircled by an air-belt which admits air into the chamber through various holes, and there are arrangements for heating the air as well as the upper part of the chamber itself. Disinfecting gases or vapours may be admitted at the same time.

The claim is for the arrangement of tiers, as described, and the specification is accompanied by one sheet of drawings.—B.

Improvements in Apparatus for Separating Liquids from Solid Matters suspended therein. J. Sawrey and H. Collet, London. Eng. Pat. 5529, March 31, 1891.

IN an upright cylindrical vessel a number of partitions of hopper-like shape are arranged, with perforations through their conical sides, and each centre opening provided with a long spout approaching the centre hole of the next lower hopper. The liquid enters near the lower end of the vessel, and on rising through the perforations allows the solid matters suspended therein to settle in the hoppers and slide down their inner sides, collecting in the bottom of the vessel, where they can be withdrawn.—B.

Improved Apparatus for obtaining Products of Distillation or Separating Volatile Liquids. L. J. P. Pontallié. Eng. Pat. 22,253, December 19, 1891.

THE object of the invention is to obtain the separation of liquids from a mixture of vapours, upon the principle of passing such vapours through vertical narrow spaces,

* Any of these specifications may be obtained by post by remitting *sd.*—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

whereby those which are less volatile condense at a lower level than those which are more volatile. One arrangement of the apparatus upon this system is shown in the accompanying figures, which will make the matter clear.

Fig. 1.

Fig. 2.

APPARATUS FOR DISTILLING AND SEPARATING VOLATILE LIQUIDS.

The injector D receiving steam through the valve *g* and pipe V draws the liquid from the tank O into the atomiser A, whence it reaches the narrow cooling spaces in the column above. Part of the heated spray and vapour passes through the column and is delivered by the pipe B into a condensing coil at F, whilst that part which is condensed in the lower part of the upright column runs off through the pipe C into the cistern T. Through this cistern passes a coil of pipes connected with the suction from the cistern O, by which means the distilling liquid takes up heat before reaching the atomiser. E and f are thermometers, and h is a tap for regulating the temperature, which is to be maintained at the boiling point of the distillate near the thermometer f.

Fig. 2 shows a cross section of the condensing column, the cooling spaces being more contracted as they near the upper end.

The apparatus is said to separate rapidly and accurately alcohol, benzene, toluene, &c.

One sheet of drawings and five claims.—B.

II.—FUEL, GAS, AND LIGHT.

The Luminosity of Coal-Gas Flames. Vivian B. Lewes.
Proc. Chem. Soc. 1892, No. 105, 2—8.

THE author has quantitatively studied the actions which lead to loss of luminosity in a Bunsen flame.

The volumes of varying mixtures of nitrogen and oxygen required to render 16·3 candle coal-gas non-luminous in a Bunsen burner are shown in the following table:—

Gas.	Volume of Mixture required.	Composition of Mixture.		Volume of Oxygen present in Amount required.
		Nitrogen.	Oxygen.	
1 vol.	2·30	1	Nil.	Nil.
1 vol.	2·30	5	1	0·38
1 vol.	2·27	4	1	0·45
1 vol.	2·02	3	1	0·50
1 vol.	1·19	2	1	0·50
1 vol.	1·00	1	1	0·50
1 vol.	0·50	Nil.	1	0·50

It is evident that until the percentage of oxygen reaches the amount present in the atmosphere, the diluting influence of the nitrogen is so strong that it prevents the oxygen having any practical effect in destroying luminosity; but that as soon as the quantity of oxygen present has risen above 25 per cent., then its activity has so far overcome the diluting influence of the nitrogen, that the latter has ceased to exercise any retarding influence on it.

In the case of other gases, the results are as follows:—

1 vol. of coal gas requires	0·5 vol. of oxygen.
"	1·26 vol. of carbon dioxide.
"	2·30 vol. of nitrogen.
"	2·27 air.
"	5·11 carbon monoxide.
"	12·4 hydrogen.

It is shown by experiment that dilution has the effect of destroying luminosity by greatly increasing the temperature necessary to decompose heavy hydrocarbons with liberation of carbon, so that at the temperature existing in a flame a volume of gas which undiluted will deposit 0·22 grm. of carbon, when diluted with 2·3 vols. of nitrogen, will only deposit 0·0013, but the higher the temperature, the less is the retarding action.

Experiments are next described in which the effect of the surrounding air on a flame is examined, and it is shown that, although the air introduced into a Bunsen is capable of bringing about certain changes in the flame when already burning in air, yet that it is quite unable by itself to keep the flame burning.

When a Bunsen burns under normal conditions, it has a bluish central zone, but if the air supply be largely in excess of that required for non-luminous combustion, the flame becomes smaller and fiercer with formation of a green central zone, which marks the change from a combustion in which the diluting influence of the nitrogen is still playing a certain part in causing non-luminosity, to a combustion in which the oxygen present having exceeded 0·5 vol. for each volume of gas, the nitrogen has ceased to exert any retarding influence.

By means of a platinum, platinum-rhodium thermocouple, the temperature was determined in various parts of a non-luminous Bunsen flame, burning 6 cubic feet of coal-gas per hour:—

Point in Flame.	Flame rendered Non-luminous by			Luminous Flame from Bunsen.
	Air.	Nitrogen.	Carbon Dioxide.	
$\frac{1}{2}$ inch above burner.	54	30	35	135
$1\frac{1}{2}$ inch above burner	175	111	70	421
Tip of inner cone ...	1,090	444	393	913
Centre of outer cone.	1,533	969	770	1,328
Tip of outer cone ...	1,175	1,151	951	728
Side of outer cone level with tip of inner cone.	1,333	1,236	970	1,236

A determination was made of the temperatures existing during the normal and also the "green centre" combustion of a Bunsen:—

	Blue Inner Cone.	Greenish Inner Cone.
	° C.	° C.
Tip of inner cone	1,090	1,375
Centre of outer cone	1,533	1,600
Tip of outer cone	1,175	1,545
Side of outer cone level with the tip of inner cone.	1,333	1,511

Analyses of gases extracted from luminous flames at the points at which the temperatures had been determined show that in the inner zone there is a rapid diminution in the quantity of hydrogen as the gases ascend in the centre of the flame, a slow diminution in the quantity of the unsaturated and saturated hydrocarbons, and a large increase in the quantity of carbon monoxide in the first half of the flame. Analysis also revealed the fact that the outer non-luminous zone of a flame is not an area of complete combustion, but a portion of the flame in which the rapid entrance of air cools, dilutes, and finally puts out the flame, allowing not inconsiderable amounts of methane, carbon monoxide, acetylene, and even hydrogen, to escape unburnt.

The undoubted presence of acetylene in the products escaping from the flame, and the fact that the incomplete combustion of hydrocarbon gases always gives rise to the formation of this compound, suggested the idea that it might play an important part in the changes taking place in the interior of a flame, and experiments were made to ascertain if any appreciable quantity were formed during the destruction of the hydrocarbons in the flame gases.

It would seem that in the interior of the luminous flame the hydrocarbons are at once attacked by the small proportion of air which penetrates into the inner zone, and that their incomplete combustion gives rise to acetylene, which, by the time the top of the inner non-luminous cone is reached, constitutes over 70 per cent. of the unsaturated hydrocarbons present, some of the acetylene, however, having probably been formed by the interaction of methane and carbon monoxide. A small proportion of some more stable unsaturated hydrocarbon may remain undecomposed and penetrate into the luminous zone, but the chief effect is due to the acetylene which is decomposed by the higher temperature, and the liberated carbon being for a moment heated to incandescence gives luminosity to the flame.

The author therefore regards the formation and decomposition of acetylene as the main cause of luminosity in a hydrocarbon flame, and if it be necessary, for purposes of simple description, to divide the luminous flame into zones, he thinks it would be most accurately regarded as consisting of three, viz.:—

1. The inner zone, in which the temperature rises from a comparatively low point at the mouth of the burner to about 1,000° C. at the apex of the zone; in this portion of the flame various decompositions and interactions occur, which culminate in the conversion of the heavier hydrocarbons into acetylene, carbon monoxide being also produced.

2. The luminous zone in which the temperature ranges from 1,000° C. up to a little over 1,300° C. Here the acetylene formed in the inner zone becomes decomposed by heat with liberation of carbon, which at the moment of formation is heated to incandescence by the combustion of the carbon monoxide and hydrogen, thus giving luminosity to the flame.

3. The extreme outer zone. Here, combustion being practically completed, the cooling and diluting influence of the entering air renders a thin layer of the flame non-luminous, finally extinguishing it.

This description of a luminous flame is of necessity far from complete, as it leaves out of consideration the causes which lead to the formation of the acetylene and the numerous interactions which take place between the products of combustion and the carbon in the upper zone of the flame.

The various actions which tend to cause the loss of luminosity in a Bunsen burner, in the author's opinion, may be summarised as follows:—

1. The chemical activity of the atmospheric oxygen, which causes loss of luminosity by burning up the hydrocarbons before they, in their diluted condition, can afford acetylene.

2. The diluting action of the atmospheric nitrogen, which, by increasing the temperature necessary to bring about the partial decomposition of the hydrocarbons, prevents formation of acetylene, and in this way will by itself cause non-luminosity; in the normal Bunsen flame it acts by doing this until destruction of the hydrocarbons by oxidation has taken place.

3. The cooling influence of the air introduced, which is able to add to the general result, although the cooling is less than the increase in temperature brought about by the oxidation due to the oxygen in the air.

4. In a normal Bunsen flame the nitrogen and the oxygen are of about equal importance in bringing about non-luminosity, but if the quantity of air be increased, then oxidation becomes the principal factor, and the nitrogen practically ceases to exert any influence.

In the discussion which followed, Professor Smithells directed Professor Lewes' attention to the controversy on the cause of delumination of flames which had taken place between Blochmann and Heumann (Annalen, 207, 167; Ber. 14, 1250, 1925, 2210); also to Walde's observations (Phil. Mag. (1838), 13, 88), in which delumination was effected by introducing luminous flames into atmospheres containing gases neutral to combustion. Walde sought to establish a relationship between diffusibility and deluminating effect. The abnormally great effect of carbon dioxide in destroying luminosity had been generally attributed, not to its high specific heat, but to its power of taking up carbon.

In a paper, which is in the press, it would be clearly demonstrated, he thought, that there are four distinct regions in a flame, however many gradations of chemical change there may be. He considered that the most important point in the paper which they had heard was that relating to the presence of acetylene in the flame. In his own experiments with ethylene he had also found that during luminous combustion scarcely any other hydrocarbons than acetylene are present in the aspirated gases. He was not satisfied, however, with Professor Lewes' proof of the escape of acetylene from ordinary luminous flames; whilst there was no *a priori* evidence against such an occurrence, unless the extraction of acetylene had been effected otherwise than by introducing cold aspirating tubes into the flame, it might be that the production of acetylene was a consequence of the method of experiment—it being well known that acetylene escaped freely from flames in contact with metallic surfaces. Accepting it as proved that the formation of acetylene in flames was an important

factor in the origin of luminosity, the question was by no means worked out. It remained to discover exactly what became of the acetylene.

Professor Lewes, in reply, said that the theory that carbon dioxide acted in destroying luminosity by converting ethylene into carbon monoxide and methane was, he thought, disproved, both by the experiments on the effect of heat in restoring luminosity to the flame and by the thermal changes taking place, as shown by the temperature of the diluted flame.

Undoubtedly Sir Humphry Davy went rather too far in his theory of luminous flames; but in a paper on the subject by him, in the *Phil. Mag.* for 1817, he says, "The intensity of light of flames depends principally upon the production and ignition of solid matter in combustion," also "Flame is gaseous matter heated so highly as to be luminous," and "when in flames pure gaseous matter is burnt, the light is extremely feeble," so that it seems hardly just to insist that he considered solid matter absolutely essential to luminosity.

The determination of the combustible gases escaping unburnt from the outer zone of non-luminous flames, had been made by taking a platinum tube 2 mm. in diameter, bent into a ring, and pierced on the inside with minute holes; this ring was placed round the flame, but not in contact with it, and the products of combustion were aspirated through this, so that the acetylene could not be due to the action of the tube.

The speaker regarded the conversion of the hydrocarbons into acetylene as the chief cause of luminosity in flame, because acetylene was practically the only heavy hydrocarbon present in that part of the flame where luminosity commenced, and as it was known that acetylene was an endothermic compound, which could be decomposed by detonation, it seemed highly probable that it would be readily decomposed by heat and liberate carbon.

The Baltimore Meeting of the American Institute of Mining Engineers. Eng. and Mining J. 1892, 229.

THE SIMULTANEOUS PRODUCTION OF AMMONIA, TAR, AND HEATING GAS. ALPHONSE HENNIN.

It is well known, said A. Hennin, that under certain conditions ammonia is found in the gas produced by the distillation of coal. For many years little or no importance was attached to its presence, and no attempt was made for its recovery. A. W. Hofmann was the first to establish a relation between the percentage of nitrogen in the coal and the proportion of ammonia in the coal-gas. If all the nitrogen in the coal could be converted into ammonia the value of this product would, itself, give handsome profits on the operation. Indeed, a coal containing $1\frac{1}{2}$ per cent. of nitrogen would produce per ton the equivalent of 164 lb. of ammonium sulphate, worth, at the present prices, 5 dols. In 1877, Dr. H. Grouven, of Leipzig, discovered that in a large excess of superheated steam, when the necessary conditions of temperature, time, and contact are supplied, combined nitrogen is transformed into ammonia.

Between these theoretical actions, however, and the establishment of an economical manufacturing process there were many difficulties to overcome. The practical operation had to be so conducted as to maintain the proper heat, make the conditions for the decomposition of ammonia as unfavourable as possible, and at the same time to produce such a gas as is required in the metallurgy of iron and steel, where rapidity of heating and melting with the lowest percentage of waste is of prime consideration. Mr. Hennin states that he has found that when high-pressure steam is moderately superheated and evenly distributed and diffused in the glowing mass in a gas-producer, a limited supply of air drawn into the generator is sufficient to maintain the temperature needed to admit continuously from 1 lb. to $1\frac{1}{2}$ lb. of high-pressure steam per pound of coal, and that this proportion of steam is ample to provoke the necessary reactions which transform into ammonia 50 per cent. to 60 per cent. of the total nitrogen of the coal and still to produce a gas of the following composition: CO_2 10.50 per cent.; O 1.00 per cent.; CO 20.00 per cent.; methane

and homologous compounds 4.50 per cent.; hydrogen 38.00 per cent.; nitrogen 26.00 per cent.

This gas is rather high in carbonic acid, but the total of combustible matter is considerable and the efficiency of the gas in a regenerative furnace is very high. It burns with a sharp, white-bluish flame, not without luminosity, and heats more rapidly and more economically than the ordinary Siemens gas. With well-designed producers and the proper plant, when the art of managing and controlling the heat in the different zones has been mastered, there is no difficulty in producing regularly, with the proper amount of steam, from each ton of coal, 70 lb. to 80 lb. of sulphate of ammonia, 130,000 cub. ft. to 150,000 cub. ft. of heating gas of high quality, and, in addition, some 15 gals. to 20 gals. of tar, according to the nature of the coal (this *Journal*, 1888, 735-737).

PATENTS.

An Improved Method and Apparatus for the Removal or Prevention of Smoke and Fog, and the Purification of Air in Towns and other Places, for the Heating and Ventilation of Houses and other Structures, for the Melting of Snow, and for the Extinguishing of Fire. E. Oades, Wokingham. Eng. Pat. 19,041, November 24, 1890.

For carrying out some of the objects mentioned above two sets of pipes or mains are laid under the roadway, and are provided with suitable traps or gratings through which the air or fog is drawn by means of pumps placed in any convenient position; branch pipes leading into the different apartments, and into the chimneys or fireplaces of the adjoining buildings are connected with each of the two mains. The fog and smoke pumped in from the street and from the buildings is passed into furnaces or stoves of special construction, where the smoke is consumed, and the fog or other suspended matter dissipated.

The ventilation of sewers might also be effected with an apparatus of this kind, the foul air being rendered harmless in passing through the furnaces; it is desirable, however, that separate mains, quite independent of those connected with the buildings, should be provided for this purpose.

The smoke from ordinary coal fires may be consumed without the employment of mains, by causing it to pass through a small gas stove packed with asbestos and placed in a convenient position above the grate; the hot air from the stove may be passed between two corrugated plates, forming an overmantel, so that the greater part of the heat would be utilised.—F. S. K.

Improvements in Gas-Producing Apparatus for Thermal Motors. G. F. Redfern, London. From "La Société Anonyme des Moteurs Thermiques Gardie," Nantes, France. Eng. Pat. 19,047, November 24, 1890.

The improved gas producer is specially applicable for use with the gas engine previously described (Eng. Pat. 2649 of 1889), its principal feature being that the gas is produced under pressure (up to several atmospheres); this is effected by having air-tight doors to the ash-pit and to the openings communicating with the hearth. The fuel (coal or anthracite) is added continuously by means of a hopper, which is provided with an air-tight cover above, and at the lower part with a large cock. The air necessary for the combustion of the fuel is forced under the grate with the aid of a steam injector, the heat of the generated gas being used for the production of steam for working the gas producer. There are four claims and two sheets of drawings.—F. S. K.

Improvements in the Generation and Combustion of Gas for Smelting and Heating Purposes, and in Appliances connected therewith. J. Hargreaves, Widnes. Eng. Pat. 1386, January 26, 1891.

SOLID fuel, such as coal, coke, or charcoal, is fed into a closed chamber and is there ignited; part of a measured quantity of a mixture of hot air and steam (or hot air alone)

under pressure is then brought into contact with the ignited fuel, so that a combustible gas is generated in the chamber. This gas is then led to the melting hearth, and is there burnt with the aid of the remainder of the definite quantity of heated air, the flame passing over the substance to be heated or melted. A chamber filled with chequer brickwork, which serves as a heat regulator and air and steam superheaters, are employed in connexion with the rest of the apparatus.—F. S. K.

Improvements in the Manufacture and Distribution of Gaseous Fuel, and in Arrangements and Apparatus therefor. J. W., A. R., and J. Ormiston, Glasgow. Eng. Pat. 1909, February 3, 1891.

THE apparatus employed for the production of the gaseous fuel consists of a large cupola or chamber, like that of a blast furnace, which is provided with twyers, charging appliances, &c., in the usual way. Instead of ordinary coal, any carbonaceous materials which contain a large proportion of earthy matter, such as poor shales, or mixtures of such minerals, may be employed. A certain amount of limestone, blast-furnace slag, or other suitable substance is mixed with the charge in order to form a fluid slag with the earthy matters; this slag is tapped off at the bottom of the furnace when necessary, without interrupting the process of gas-making.

The advantages claimed for this method of producing gas are, amongst others, that carbonaceous materials hitherto regarded as valueless may be employed, and that the labour involved in removing the "cinder" or ashes is entirely done away with.

The gas may be distributed by means of underground tunnels pierced through rock or dense strata, and communicating with vertical shafts or branches at suitable points.—F. S. K.

Improvements in Apparatus for Carburetting Gas or Air, or for Distilling, Evaporating, or Concentrating. F. Lennard, East Greenwich. Eng. Pat. 3916, March 4, 1891.

THE apparatus here described is for use in cases when it is desired to distil off the volatile constituents of a liquid, and at the same time to utilise the vapours for carburetting air or gas. The liquid to be distilled is first warmed by the hot vapours produced at a later stage of the operation, and then caused to flow down a series of vertical tubes which are heated by steam or hot air; in this way a large surface is exposed, and the more volatile constituents are readily vaporised. When air or gas is to be carburetted it is admitted under pressure, and caused to pass upwards through the heated vertical tubes down which the liquid is flowing.—F. S. K.

Improvements in the Purification of Water-Gas, or other Producer Gas from Sulphur Compounds. C. F. Claus, London. Eng. Pat. 4279, March 10, 1891.

THE gas to be purified is passed through iron cylinders or boxes, filled with iron or copper; the metal may be employed in the form of granules or scrap, but it is preferable to prepare it in a spongy condition by reducing it from the oxide with hydrogen or water-gas. The iron cylinders or boxes are either set in brickwork, so that they can be heated from the outside, or else they are lined inside with brickwork so that they may be heated by hot gases internally, such heating being necessary when the process is first started. The hot gas, at a temperature of from 500°–700° C. as it leaves the producer, is passed through two or more purifiers, and is there deprived of its sulphur compounds; the heat of the gas and that generated by the chemical action is sufficient to maintain the requisite temperature when the process is in full operation. When the purifier is spent, or partly spent, it is disconnected and cold or hot air is passed through it until the whole of the

sulphide of the metal has been converted into oxide; the oxide is then reduced to metal by treating it with water-gas at a suitable temperature, and the purifier is then ready for use again.—F. S. K.

An Improved Method of and Apparatus for the Purification of Smoke in Chimneys. E. R. Salwey, Bristol. Eng. Pat. 4565, March 14, 1891.

See under XVIII.—B., page 260.

Improvements in or relating to Gas Generators for Motor Engines. A. J. Boulton, London. From "Compagnie des Fonderies et Forges de l'Homme" and A. Leucachez, Paris, France. Eng. Pat. 4798, March 17, 1891.

THE object of this invention is to obtain generator gas which can be employed in the place of ordinary coal-gas for feeding motor engines; for this purpose certain improvements have been made in the ordinary apparatus in order to produce a richer gas.

The air for supplying the blast of the generator is first passed through a tubular superheater, in which its temperature is raised to 200°–300° by the hot generator gas; it is then passed under pressure into a hollow chamber situated under the generator, and partly filled with hot water, which, coming from the cylinder of the engine, is caused to spray against the metallic portion of the grate, whence it falls to the bottom of the chamber. The air, thus saturated with water and superheated, is now forced through the generator, and in this way a combustible gas, rich in hydrogen, is produced. This gas is first passed through the air superheater, whereby it is cooled, and then through a scrubber or washer of the usual form. It sometimes happens that the grate loses its brightness to a certain extent owing to the loss of heat which is involved in producing the generator-gas; this difficulty is overcome by surrounding the grate with a coil- or ring-burner, fed with gas under pressure from a separate gasometer.

—F. S. K.

Improvements in Means of Consuming Smoke. S. Hoyle and A. Haslam, Radeliffe. Eng. Pat. 4912, March 19, 1891.

By this invention a box or chamber is provided extending beneath and up the back of the fire-bridge and communicating with the furnace, above the fire-bars, by a set of parallel passages; below the bars, by a wide opening. In working, heated gases are drawn in through these inlets and issue at a grided outlet just behind the top of the fire-bridge; there they come in contact with the smoke and consume it.—D. A. L.

Improvements in the Art of Manufacturing Illuminating Gas. W. H. Munns, London. From E. de Beauharnais, New Bedford, U.S.A. Eng. Pat. 5212, March 24, 1891.

CRUDE petroleum is allowed to drip through a perforated cover on to ground corn-cobs, on the surface of which a small quantity of ashes, made from the wood and bark of the white ash-tree, is placed. After leaving the oil in contact with this mixture for about 24 hours, it is mixed with rain-water and introduced into a U-shaped retort together with heated air and steam; the gas produced in this way passes along one horizontal limb of the retort, and, at the bend, comes into the current of a jet of steam, which is directed towards the outlet of the other limb, and which accelerates the passage of the gas from the retort; the gas is then carburetted in the usual manner.

It is stated that the gas produced from petroleum treated as described above is a very superior illuminating gas, but what the chemical effect of this treatment may be is not known.—F. S. K.

Improvements in Carburettors. M. Merichenski, London.
Eng. Pat. 7188, April 25, 1891.

THE carburettor consists of a square, rectangular, or cylindrical vessel made of glass, glazed earthenware, or some other suitable material; it is packed with a light absorbent wood, crushed into a mass and saturated with oil. The vessel is divided by partitions in such a way that the gas to be carburetted passes through as great a length as possible of the saturated wood. A portion of the last channel through which the gas passes is filled with charcoal, or with mineral wool, so that it acts as a cooling or condensing chamber, in which the gas is freed from surplus carbon. The apparatus is charged with oil at intervals as required, either from a can or from a reservoir. The carburettor is designed to be introduced locally in buildings; it is stated that by its use the illuminating power of ordinary coal-gas is raised from 12 to 50 per cent., and that the carbon monoxide and sulphurous gases are wholly consumed.

—F. S. K.

Improvements in or Relating to Magnesium Flash Lights.
R. Haddan, London. From F. H. F. Engel, Hamburg, Germany. Eng. Pat. 7487, April 30, 1891.

See under XXI., page 267.

Process of and Apparatus for the Manufacture of Gas.
W. Fairweather, Glasgow. From "The Acme Liquid Fuel Company," New York, U.S.A. Eng. Pat. 21,881, December 15, 1891.

THIS invention relates to the manufacture of heating and illuminating gas from hydrocarbons, from hydrocarbons and water, and from hydrocarbons and hydrogen.

The hydrocarbon is first heated by means of a steam coil, then passed into a vaporiser, and finally superheated; the fixed gas obtained in this way may then be mixed with superheated steam. When hydrogen is employed it is mixed with the hydrocarbon vapour before the latter is superheated. For details the original must be consulted.

There are 50 claims and two sheets of drawings.—F. S. K.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

On Picene. R. Lescipan. Bull. Soc. Chim. 1891, 6,
258—259.

AMONGST the products resulting from the action of ethylene bromide on naphthalene in presence of aluminium chloride was a hydrocarbon described by Roux as boiling at 450°, and crystallising in scales melting at 300°. In taking up the further study of this substance the author found much difficulty in freeing it from dinaphthyl and naphthalene derivatives, but after several distillations and crystallisations the melting point rose to 337°, and the substance thus purified was found to resemble the hydrocarbon termed picene described by Burg. Its close affinity to picene was shown by the formation and analysis of the bromide, a substance melting at 294°, insoluble in chloroform, but soluble in xylene. Burg gives $C_{22}H_{14}$ as the formula for picene.—G. H. B.

The Melting Points of Mixtures of Hydrocarbons.
L. Vignon. Compt. Rend. 1891, 113, 133—136.

THE melting point of mixtures of naphthalene and diphenyl-naphthalene and phenanthrene, naphthalene and triphenylmethane, diphenyl and phenanthrene, diphenyl and triphenylmethane in proportions varying from 1 molecule of the one to 4 molecules of the other is in all cases lower than the mean of the melting points of the two bodies

composing the mixture. In each case a minimum melting point is reached, corresponding to the following molecular proportions:—

	Melting Point.
Naphthalene and diphenyl..... $C_{10}H_8$, $(C_{12}H_{10})_2$	50° C.
Naphthalene and phenanthrene..... $(C_{10}H_8)_2$, $C_{11}H_{10}$	53° C.
Naphthalene and triphenylmethane..... $C_{10}H_8$, $CH(C_6H_5)_3$	53° C.
Diphenyl and phenanthrene..... $(C_{12}H_{10})_2$, $C_{11}H_{10}$	64° C.
Diphenyl and triphenylmethane..... $(C_{12}H_{10})_2$, $CH(C_6H_5)_3$	50° C.

In the majority of these cases the mixture consists of 2 molecules of the more fusible and 1 molecule of the less fusible hydrocarbon. Mixtures of anthracene with diphenyl, triphenylmethane, phenanthrene, and naphthalene do not show such regularities. The melting point of the mixture is higher than the mean of those of the components and rises fairly regularly with an increase in the proportion of anthracene.—C. A. K.

The Manufacture of Charcoal from Sawdust, Wood Shavings, and the like, and the Treatment of Wine, Alcohol, Brandy, Cider, Beer, and other Matters therewith. F. L. Calmant, Paris, France. Eng. Pat. 3978, March 5, 1891.

See under XVII., page 257.

An Improved Coke Furnace or Oven. K. Lares, Karwin, Austria. Eng. Pat. 17,371, October 12, 1891.

THE coke oven described in this patent with the aid of five sheets of drawings is designed for working with large charges, the main object of the invention being to combine steady working with rapid coking, and at the same time to prevent as much as possible the deterioration of the oven.

The gases from the combustion chamber pass through a series of flues, and are thus brought into contact with the outer surfaces of the side walls, of the hearth, and of a part of the crown of the furnace; the air necessary for their complete combustion is admitted through suitable passages.

IV.—COLOURING MATTERS AND DYES.

Preparation of α -Trinitrotoluene. C. Häussermann.
Zeits. f. angew. Chem. 1891, 661—662.

TOLUENE can of course be directly converted in a single operation into the 1 : 2 : 4 : 6 trinitro-derivative, but it is more advantageous to start with the *o*-*p*-dinitrotoluene, which is prepared by allowing a mixture of 75 parts of 91—92 per cent. nitric acid and 150 parts of 95—96 per cent. sulphuric acid to run in a thin stream into 100 parts of *p*-nitrotoluene while the latter is continuously stirred and the temperature maintained between 60°—65°; as soon as the acid has been run in, the mixture is heated for half all
